FOREWORD

This manual provides information for the proper servicing of the 1961 Thunderbird. The descriptions and specifications contained in this manual were in effect at the time the manual was approved for printing. The Ford Division of Ford Motor Company reserves the right to discontinue models at any time, or change specifications or design, without notice and without incurring obligation.
THUNDERBIRD IDENTIFICATION

Figure 1 illustrates a Thunderbird rating plate and its elements. The rating plate is attached to the left door front pillar.

MODEL YEAR
The number "1" designates 1961.

ASSEMBLY PLANT
The letter "Y" designates the Lincoln plant at Wixom, Mich.

MODEL
71 Tudor Hardtop
73 Convertible

ENGINE
Z 390 cubic inch V-8

CONSECUTIVE UNIT NUMBER
The assembly plant, with each model year, begins with consecutive unit number 100001 and continues on for each unit built.

ENGINE AND EXHAUST SYSTEM

PART 1-1 ENGINE ........................................... 1-2

PART 1-2 EXHAUST SYSTEM ................................. 1-45

PART 1-3 SPECIFICATIONS ................................. 1-47
1 DESCRIPTION

The Thunderbird 390 Special V-8 engine (Figs. 1 and 2) has a 4.05-inch bore and a 3.78-inch stroke and a total piston displacement of 390 cubic inches. It has a compression ratio of 9.6:1. The patent plate symbol for the engine is "Z."

MANIFOLDS

The intake manifold has a passage through the center section and under the carburetor, through which hot exhaust gases are directed to assist in vaporizing the incoming fuel charge (Fig. 3). The exhaust gases are directed into the intake manifold by a thermostatically controlled exhaust valve (Fig. 4).
valve is located at the outlet of the right exhaust manifold. When the valve is in the closed or heat on position, part of the exhaust gases are directed from the right exhaust manifold, through the heat riser passage, to the left exhaust manifold. When the valve is open or in the heat off position, more of the exhaust gases from the right manifold are permitted to flow directly out of the exhaust system in the normal manner.

The intake manifold has two sets of fuel passages, each with its own separate inlet connection to the carburetor (Fig. 5). The right barrels of the carburetor feed Nos. 1, 4, 6, and 7 cylinders and the left barrels feed Nos. 2, 3, 5, and 8 cylinders. The distributor is mounted at the left front of the intake manifold. Warm air for the automatic choke is drawn from the heat chamber of the right exhaust manifold (Fig. 6).

**CYLINDER HEADS**

The cylinder head assemblies contain the valves and the valve rocker arm shaft assembly. The combustion chambers are machined in the head. Valve guides are an integral part of the head. The valves are arranged from front to rear on both banks E-I-E-I-E-I-E-I (Fig. 7).

**CYLINDER BLOCK**

The cylinders are numbered from front to rear, on the right bank 1, 2, 3 and 4 and on the left bank 5, 6, 7 and 8. The firing order is 1-5-4-2-6-3-7-8.

The oil pump, mounted inside the oil pan at the front, is driven by the distributor through an intermediate drive shaft.

The crankshaft is supported by five main bearings. Crankshaft end thrust is controlled by the flanges of the No. 3 main bearing.

The pistons have two compression rings and one oil control ring. The top compression ring is chrome-plated and the lower compression ring is phosphate-coated. The oil control ring assembly consists of a serrated spring and two chrome-plated steel rails.

**VALVE TRAIN**

The intake and exhaust valve assemblies are the rotating-type which
rotate each time the valve opens and closes.

The push rods are solid steel with oil cushioned sockets.

The camshaft is supported by five bearings pressed into the block. It is driven by a sprocket and timing chain in mesh with a sprocket on the crankshaft. Camshaft end play is controlled by a thrust button and spring located between the camshaft sprocket bolt and the cylinder front cover. An eccentric, bolted to the front end of the camshaft, operates the fuel pump.

Hydraulic valve lifters are used which provide zero valve lash. The operation and parts identification of the hydraulic valve lifters are shown in Fig. 8.

When the valve is closed, the lifter assembly is on the base circle of the camshaft lobe and the valve push rod is in its lowest position. With the lifter assembly in this position, the plunger spring expands forcing the plunger upward. This action is transmitted to the valve rocker arm via the valve push rod until there is solid contact between the valve and the valve end of the valve rocker arm (zero valve lash). In this position, the oil hole in the lifter and plunger is indexed with the lifter oil gallery and oil is forced under pressure into the plunger. This creates a pressure differential above and below the valve disc. The high pressure above the valve disc forces the valve disc open and the oil fills the area below the plunger, equalizing the pressure on each side of the valve disc.

Whenever clearance between the valve and the valve rocker arm tends to be present, the plunger spring expands forcing the plunger until there is solid contact between all parts of the valve train mechanism.

As the camshaft rotates (valve opening), the valve lifter is raised and the sudden increase in oil pressure below the plunger forces the valve disc closed and the lifter becomes a hydraulic ram. During this period, a slight leakage of oil from below the plunger occurs. As the high point on the camshaft lobe rotates past the lifter, the push rod forces the valve lifter down and reseats the valve. The pressure on the oil below the plunger is relieved and the valve disc opens so that the chamber can again be filled. This cycle is repeated for each revolution of the camshaft.

FIG. 9—Lubrication System

LUBRICATION SYSTEM

Oil from the oil pan sump, located in the front of the oil pan, is forced through the pressure-type lubrication system (Fig. 9) by a rotor oil pump. A spring-loaded relief valve in the pump limits the maximum pressure of the system. Oil relieved by the valve is directed back to the intake side of the pump.

All the oil discharged by the pump passes through a full flow-type filter before it enters the engine. The filter is mounted in a vertical position at the lower left front of the engine. A relief valve in the filter permits oil to bypass the filter if it becomes clogged.

From the filter, the oil flows into the main oil gallery which is located in the center of the valve push rod chamber floor. The oil gallery supplies oil to each individual camshaft bearing, through drilled passages in the block. Passages are drilled from each camshaft bearing to each main bearing. Number 1 camshaft bearing feeds No. 1 main bearing, and No. 2 camshaft bearing feeds No. 2 main bearing, etc. The oil then flows through notches or grooves in the main bearings to lubricate the crankshaft journals. A jiggle pin in the main oil gallery front plug allows any air that may be trapped in the oil to escape. The timing chain and sprockets are splash lubricated by oil from the jiggle pin.

The crankshaft is drilled from the main bearings to the connecting rod bearings.

A small groove is located in the connecting rod at the mating face where the cap contacts the connecting rod. This groove is used as an oil squirt hole for cylinder wall lubrication. Oil from the connecting rod squirt hole lubricates the opposite cylinder wall. For example, the No. 1 connecting rod oils No. 5 cylinder, etc. As the crankshaft turns, the hole in the connecting rod bearing aligns with the hole in the journal causing a direct squirt of oil onto the cylinder wall.

Oil passages are drilled from the main oil gallery to each valve lifter oil gallery. Oil from here feeds the valve lifter assemblies. A reservoir at each valve lifter bore boss traps oil so that oil is available for valve lifter lubrication as soon as the engine starts.
An oil passage is drilled from No. 2 camshaft bearing web to the left cylinder head between Nos. 5 and 6 cylinders to lubricate the valve rocker arm shaft assembly (Fig. 10). The oil passage in the cylinder head is drilled from the cylinder head bolt bore to the No. 2 valve rocker arm shaft support.

The oil flows through the valve rocker arm shaft through drilled holes in each valve rocker arm to lubricate the bushing and both ends of the valve rocker arm. The excess oil spirals down the rotating push rods and lubricates the push rod seats. The right valve rocker arm shaft assembly is similarly lubricated from No. 4 camshaft bearing via the No. 4 valve rocker arm shaft support.

A baffle located under the valve rocker arm shaft assembly shields the valve stems from oil splash. Excess oil is returned to the oil pan through drain-back holes located at each end of the cylinder head and in the push rod chamber floor.

**POSITIVE CRANKCASE VENTILATION SYSTEM**

Ventilating air is drawn into the engine through the breather cap by a regulator valve located in the intake manifold. The valve regulates the amount of air to meet changing operating conditions. The air is returned to the intake manifold through an exhaust tube which extends from the crankcase ventilation outlet at the rear of the intake manifold to a spring-loaded regulator valve installed in the intake manifold (Fig. 11).

When the engine is shut off, the spring forces the valve off its seat. This closes off the inlet to the valve housing.

During idle, intake manifold vacuum is high. The high vacuum overcomes the tension of the spring pressure and seats the valve (Fig. 12). With the valve in this position, all the ventilating air passes through a calibrated orifice in the valve. With the valve seated there is minimum ventilation. As engine speed increases and manifold vacuum decreases, the spring forces the valve off its seat and to the full open position. This increases the flow of ventilating air.

From the breather cap, the air flows into the front section of the valve push rod chamber where there are few contaminating vapors. Here,
the incoming air has a chance to warm up before contacting contaminating vapors originating in the crankcase. Warm ventilating air minimizes the formation of crankcase sludge.

The ventilating air is directed by a baffle, located on the underside of the intake manifold, upward into the front of both valve rocker arm chambers. The baffle also directs air to the front of the lower crankcase and into the timing chain chamber.

Air from the valve rocker arm chamber and from the crankcase flows into the rear of the valve push rod chamber. All air is then drawn through the regulator valve and is discharged into the intake manifold.

**COOLING SYSTEM**

The coolant is drawn from the bottom of the radiator by the water pump which delivers the coolant to the cylinder block (Fig. 13).

The coolant travels through cored passages to cool the entire length of each cylinder wall. Upon reaching the rear of the cylinder block, the coolant is directed upward into the cylinder heads where it cools the combustion chambers, valves, and valve seats on its return to the front of the engine.

**FIG. 13—Cooling System**

The coolant from each cylinder head flows through the water passages in the intake manifold and past the water thermostat, if it is open, into the radiator supply tank. If the thermostat is closed, a small portion of the coolant is returned to the water pump for recirculation. The entire system is pressurized to 13-15 psi.

**2 ENGINE TROUBLE DIAGNOSIS**

Engine performance complaints usually fall under one of the basic headings listed in the “Engine Trouble Diagnosis Guide.” When a particular trouble can not be traced to a definite cause by a simple check, the possible items that could be at fault are listed in the order of their probable occurrence. Check the items in the order listed. For example, under Poor Acceleration, the ignition system is listed as a probable cause of the trouble. All the ignition system items that affect acceleration are listed. Check all these items before proceeding to the next probable cause.

**ENGINE TROUBLE DIAGNOSIS GUIDE**

| ENGINE WILL NOT CRANK | Check the fuel supply. If there is sufficient fuel in the tank, the cause of the trouble probably lies in either the ignition or the fuel system. To determine which system is at fault perform the following test: Disconnect a spark plug wire. Check the spark intensity at the end of the wire by installing a terminal adapter in the terminal of the wire. |
| ENGINE CRANKS NORMALLY, BUT WILL NOT START | The cause of this trouble is usually in the starting system (Part 10-2). If the starting system is not at fault, check for a hydrostatic lock or a seized engine as follows: Remove the spark plugs, then attempt to crank the engine with the starter. If the engine cranks, it indicates that water is leaking into the cylinders. Remove the cylinder head(s) and inspect the gaskets(s) and/or head(s) for cracks. Examine the cylinder block for cracks. |

<tbody>
<tr>
<td>to be checked. Hold the adapter approximately ¾ inch from the exhaust manifold and crank the engine.</td>
<td></td>
<td>Idle fuel mixture needles not properly adjusted. Engine idle speed set too low. The choke not operating properly. Float setting incorrect. Fuel inlet system not operating properly. Dirt or water in fuel lines or in the fuel filter.</td>
</tr>
<tr>
<td>IF THERE IS NO SPARK OR A WEAK SPARK AT THE SPARK PLUGS</td>
<td>If fuel is not reaching the carburetor, check: The fuel filter. The fuel pump. The carburetor fuel inlet line for obstructions. The fuel pump flexible inlet line for a collapsed condition. The fuel tank line for obstructions. The fuel tank vent. If fuel is reaching the carburetor, check: The fuel inlet system including the fuel inlet needle and seat assembly, and the float assembly.</td>
<td></td>
</tr>
<tr>
<td>The cause of the trouble is in the ignition system. To determine if the cause of the trouble is in the primary or the secondary circuit, remove the coil high tension lead from the top of the distributor and hold it approximately ¾ inch from the cylinder head. With the ignition on, crank the engine and check for a spark. If the spark at the coil high tension lead is good, the cause of the trouble is probably in the distributor cap or rotor. If there is no spark or a weak spark at the coil high tension lead, the cause of the trouble is probably in the primary circuit, coil to distributor high tension lead, or the coil.</td>
<td></td>
<td>Carburetor icing. Fuel pump defective. Dirt in the carburetor, not allowing fuel to enter or be discharged from the idle system.</td>
</tr>
<tr>
<td>IF THERE IS A GOOD SPARK AT THE SPARK PLUGS</td>
<td>IGNITION SYSTEM</td>
<td>Leakage in the high tension wiring.</td>
</tr>
<tr>
<td>Check the spark plugs. If the spark plugs are not at fault, check the following items: AUTOMATIC CHOKE</td>
<td></td>
<td>MISSSES STEADILY AT ALL SPEEDS</td>
</tr>
<tr>
<td>Check the position of the choke plate. If the engine is hot, the plate should be open. If the plate is not open, the engine will load up due to the excessively rich mixture and will not start. If the engine is cold, the plate should be closed. If the plate is not operating properly, check the following items: The choke linkage for binding. The fast idle cam for binding. Thermostatic spring housing adjustment.</td>
<td>Isolate the miss by operating the engine with one cylinder not firing.</td>
<td></td>
</tr>
</tbody>
</table>

CONTINUED ON NEXT PAGE
### ENGINE TROUBLE DIAGNOSIS GUIDE (Continued)

| ENGINE RUNS, BUT MISSES (Continued) | This is done by operating the engine with the ignition wire removed from one spark plug at a time, until all cylinders have been checked. Ground the spark plug wire removed.  
If the engine speed changes when a particular cylinder is shorted out, that cylinder was delivering power before being shorted out. If no change in the engine operation is evident, the miss was caused by that cylinder not delivering power before being shorted out. In this case, check the:  
IGNITION SYSTEM  
If the miss is isolated in a particular cylinder, perform a spark test on the ignition lead of that cylinder.  
If a good spark does not occur, the trouble is in the secondary circuit of the system. Check the spark plug wire and the distributor cap.  
If a good spark occurs, check the spark plug. If the spark plug is not at fault, a mechanical component of the engine is probably at fault.  
ENGINE  
Perform a compression test to determine which mechanical component of the engine is at fault (page 1-13). |
| --- | --- |
| MISSES ERRATICALLY AT ALL SPEEDS | EXHAUST SYSTEM  
Exhaust system restricted.  
IGNITION SYSTEM  
Defective breaker points, condenser, secondary wiring, coil, or spark plugs.  
High tension leakage across the coil, rotor, or distributor cap. |
| ROUGH ENGINE IDLE | FUEL SYSTEM  
Engine idle speed set too low.  
Idle fuel mixture needles not properly adjusted.  
Float setting incorrect.  
Air leaks between the carburetor and the manifold and/or fittings.  
Power valve leaking fuel.  
Idle fuel system air bleeds or fuel passages restricted.  
Fuel bleeding from the accelerating pump discharge nozzles.  
Secondary throttle plates not closing. |
| --- | --- |
| FUEL SYSTEM | COOLING SYSTEM  
Check the cooling system for internal leakage and/or for a condition that prevents the engine from reaching normal operating temperature. |
| -- | ENGINE  
Perform a compression test to determine which mechanical component of the engine is at fault (page 1-13).  
FUEL SYSTEM  
Idle fuel mixture needles not properly adjusted.  
IGNITION SYSTEM  
Excessive play in the distributor shaft.  
Worn distributor cam. |
| MISSES AT IDLE ONLY | ENGINE  
Perform a compression test to determine which mechanical component of the engine is at fault (page 1-13).  
FUEL SYSTEM  
Power valve clogged or damaged.  
Low or erratic fuel pump pressure.  
Fuel inlet system not operating properly.  
Restricted fuel filter. |
| MISSES AT HIGH SPEED ONLY | COOLING SYSTEM  
Engine overheating.  
FUEL SYSTEM  
Power valve leaking fuel.  
Idle fuel system air bleeds or fuel passages restricted.  
Fuel bleeding from the accelerating pump discharge nozzles.  
Secondary throttle plates not closing. |

<tr>
<td>Cracked cylinder head or block, or warped cylinder head or block gasket surface.</td>
</tr>
<tr>
<td><strong>NOISY HYDRAULIC VALVE LIFTER</strong></td>
</tr>
<tr>
<td>A noisy valve lifter can be located by operating the engine at idle speed and placing a finger on the face of the valve spring retainer. If the lifter is not functioning properly, a shock will be felt when the valve seats.</td>
</tr>
<tr>
<td>Another method of identifying a noisy lifter is by the use of a piece of hose. With the engine operating at idle speed, place one end of the hose near the end of the valve stem and the other end to the ear and listen for a metallic noise. Repeat this procedure on each intake and exhaust valve until the noisy lifter(s) has been located.</td>
</tr>
<tr>
<td>The most common causes of hydraulic valve lifter troubles are dirt, gum, varnish, carbon deposits, and air bubbles.</td>
</tr>
<tr>
<td>Dirt in the lifter assembly can prevent the disc valve from seating, or it may become lodged between the plunger and body surfaces. In either case, the lifter becomes inoperative due to failure to &quot;pump-up,&quot; or because the internal parts are no longer free to function properly. When dirt is found to be responsible for lifter malfunction, remove the lifter assembly and thoroughly clean it. Recommended engine oil and filter change intervals should be followed to minimize lifter problems caused by dirt.</td>
</tr>
<tr>
<td>Deposits of gum and varnish cause similar conditions to exist which may result in lifter malfunction. If these conditions are found to be present, the lifter should be disassembled and cleaned in solvent to remove all traces of deposits.</td>
</tr>
<tr>
<td>Air bubbles in the lubricating oil, caused by an excessively high or low oil level, may likewise cause lifter malfunction. A damaged oil pick up tube may allow air to be drawn into the lubricating system. To check for the presence of air, remove a valve rocker arm cover and note the condition of the oil as it flows from the valve rocker arm shaft assembly. Perform corrective action as required to remove air from the lubricating oil.</td>
</tr>
</tbody>
</table>
TUNE-UP

The Tune-Up Schedule (Table 1) is for either an A, B, or C tune-up. Perform all operations in the sequence listed. The recommended mileage interval for an A tune-up is 4000 miles, for a B tune-up it is 8000 miles, and for a C tune-up it is 12,000 miles. For a detailed description of an operation procedure, refer to the operation number under "Tune-Up Procedure."

TUNE-UP PROCEDURE

The tune-up is divided into 3 major parts.

</table>
pitted electrodes, or other signs of failure. Replace as required.

Set the gap of all serviceable or new plugs to 0.032-0.036 inch by bending the ground electrode (Fig. 15).

After the gap has been adjusted, check the plugs on a testing machine. Compare the sparking efficiency of the cleaned and gapped plug with a new plug. Replace the plug if it fails to meet requirements. Apply a coating of oil to the shoulder of the plug where the insulator projects through the shell, and to the top of the plug, where the center electrode and terminal project from the insulator. Place the spark plug under pressure. Leakage is indicated by air bubbling through the oil. If the test indicates compression leakage, replace the plug. If the plug is satisfactory, wipe it clean.

Install the spark plugs and torque them to 15-20 ft-lbs.

2. Take A Compression Reading Of Each Cylinder. Remove the spark plugs. Remove the coil high tension lead at the distributor cap. Set the primary throttle plates and choke plate in the wide open position.

Install a compression gauge in No. 1 cylinder.

Using a remote starter switch, crank the engine several times and record the highest reading recorded. Note the number of compression strokes required to obtain the highest reading.

Repeat the test on each cylinder, cranking the engine the same number of times for each cylinder as was required to obtain the highest reading on the No. 1 cylinder.

A variation of ± 20 pounds from specified pressure of 180 psi is satisfactory. However, the compression of all cylinders should be uniform within 10 pounds.

A reading of more than the allowable tolerance above normal indicates excessive deposits in the cylinder.

A reading of more than the allowable tolerance below normal indicates leakage at the cylinder head gasket, piston rings, or valves.

A low even compression in two adjacent cylinders indicates a cylinder head gasket leak. This should be checked before condemning the rings or valves.

To determine whether the rings or the valves are at fault, squirt the equi-
Be sure the fuel-flow arrow on the filter are pointed toward the outlet of the filter (toward the carburetor).

7. Check And Adjust Carburetor Fuel Level. Check and set the floats. Refer to “Bench Adjustments” (Part 3-2).

8. Clean The Distributor Cap And Rotor. Disconnect the coil high tension lead and the spark plug wires at the distributor cap. Remove the distributor cap and rotor.

Clean the inside of the distributor cap and clean the rotor using a mild cleaning solvent or mineral spirits and a soft bristle brush. Remove dirt or corrosion from the sockets of the distributor cap. Inspect the cap for cracks, burned contacts, or permanent carbon tracks. Inspect the rotor for cracks or a burned tip. Replace the cap and/or rotor if they are defective.

9. Lubricate The Distributor Cam, Lubricating Wick, And The Distributor Bushing. Apply a light film of high-temperature, non-fiber grease to the distributor cam. Do not use engine oil.

Saturate the lubricating wick with SAE 10W engine oil.

Squirt a few drops of SAE 10W engine oil into the distributor oil cup.

10. Clean Battery Cables And Terminals. Disconnect the battery cables. Wash the battery including the terminals and battery carrier in cold water using a stiff bristle brush. If the battery is extremely dirty, use a baking soda solution. Inspect the battery cables for corrosion, fraying, or breaks. Apply grease to the battery terminals after cleaning. Connect and properly tighten the cable clamps.

11. Clean Positive Crankcase Ventilation System. Remove the crankcase ventilation regulator valve, exhaust tube, and connections. Disassemble the valve. Clean the valve and exhaust tube in clean carburetor solvent and dry them with compressed air. Clean the rubber hose connections with a low volatility petroleum base solvent and dry them with compressed air.

INSTRUMENT CHECKS

Always follow the instructions of the test unit manufacturer when performing instrument checks. All the tests except checking distributor spark advance can be made in-chassis. Perform the tests in the sequence listed.

12. Check Battery State of Charge. The battery state of charge can be checked by measuring the battery electrolyte solution specific gravity (hydrometer) or by measuring the voltage of the battery cells on open circuit (no current flow) with a battery charge tester.

If a hydrometer is used, a specific gravity of 1.275-1.285 indicates a fully charged battery. 1.230-1.240 indicates approximately 60% charge. If the specific gravity varies more than 0.025 between cells, the battery should be replaced.

Refer to Part 10-1 which describes in detail the procedure to be followed.

13. Check And Adjust Breaker Point Dwell. If the contacts are excessively out of alignment, replace the breaker point assembly. Do not attempt to align used breaker points. Install a new breaker point assembly if necessary (Part 2-2).

Use a dwell meter only to check the gap of used breaker points. The roughness of used breaker points makes an accurate gap reading or setting with a feeler gauge impossible. Check and set the contact dwell to specification (Part 2-3) by following the instructions of the meter manufacturer. Always clean used points before adjusting.

14. Check And Adjust Spark Advance. Refer to the procedure in Part 2-1.

After the spark advance has been checked and adjusted, install the rotor and position the distributor in the block so that the rotor is aligned with the mark previously scribed on the distributor body, and the marks on the body and engine block are in alignment. Install the distributor retaining screw(s). Install the distributor cap. Insert each distributor wire in the proper distributor cap socket. Be sure the wires are forced all the way down into their sockets. The No. 1 socket is identified on the cap. Starting at the No. 1 socket, install the wires in the direction of distributor rotation (counterclockwise) in the firing order (1-5-4-8-6-3-7-2). Push all weather seals into position.

15. Perform A Spark Intensity Test Of Each Spark Plug Wire. Check the spark intensity of one wire at a time. Install a terminal adapter in the terminal of the wire to be checked. Hold the adapter approximately \( \frac{3}{8} \) inch from the exhaust manifold and crank the engine with a remote starter switch. The spark should jump the gap regularly.

16. Check Fuel Pump Pressure And Capacity. Disconnect the fuel line at the carburetor. Install a pressure gauge (0-15 psi) and a petcock on the carburetor fuel inlet line (Fig. 17). Vent the system, by opening the petcock momentarily, prior to taking a pressure reading. Operate the en-

FIG. 17—Fuel Pump Pressure and Capacity Test
gine at 500 rpm. After the pressure has stabilized, it should be 4.0-6.0 psi.

Operate the engine at 500 rpm. Open the petcock and expel the fuel into a suitable container. Observe the time required to expel one pint. It should be within 20 seconds.

If the capacity is not to specifications, remove the fuel filter from the system and make another capacity check.

If the capacity is within specifications with the fuel filter removed, the fuel filter was restricted and a new one should be installed.

If the capacity is not within specifications with the fuel filter removed, the fuel pump is defective.

**WHILE ENGINE IS WARMING-UP**

Place the transmission selector lever in neutral position and set the parking brake. Start the engine and operate it at 1200 rpm for 30 minutes to stabilize engine temperatures. While the engine is warming up, perform the following operations:

17. **Clean Carburetor Air Cleaner.** Direct clean compressed air against the element in the opposite direction of normal air flow, that is, from the inside of the filter out.

Clean the air cleaner body and cover in cleaning solvent, then wipe them dry.

Do not install the air cleaner at this time.

18. **Inspect the Radiator, Hoses, and Engine For Coolant Leaks.** Inspect the radiator hoses for cracks, leaks, and a collapsed condition. Inspect the radiator and engine for external leaks.

Check for internal leakage by operating the engine at fast idle and looking for the formation of bubbles in the radiator supply tank. Oil in the supply tank may indicate leakage in the engine block or a leak in the automatic transmission oil cooler. Water formation on the oil level dipstick could be an indication of internal leakage.

19. **Check And Adjust Ignition Timing.** Disconnect the distributor vacuum line. Connect the timing light high tension lead to the No. 1 spark plug and the other two leads of the timing light to the battery terminals.

**FIG. 18—Carburetor Idle Adjustments**

Do not puncture the spark plug wire or moulded cap.

Clean the dirt from the timing marks pin on the crankshaft damper. If necessary, chalk the proper mark to improve legibility.

Operate the engine at idle speed. Be sure the engine is idling below 550 rpm so that there will be no centrifugal advance. The timing light should flash just as the proper mark lines up with the pin indicating correct timing. The operator's eye should be in line with the center of the damper and the timing pointer. Refer to Part 2-3 for the correct specifications.

**ENGINE OPERATING AT NORMAL TEMPERATURE**

20. **Adjust Accelerator Pump Link to Seasonal Position.** The over-travel lever has four holes and the accelerating pump link has two holes to control the accelerating pump stroke for different engine applications (Fig. 18). Install the accelerating pump operating rod in the No. 4 (top) hole for winter operation or in the No. 2 hole for summer operation in the over-travel lever. Install the accelerating pump operating rod in the outside hole in the accelerating pump link for all climatic conditions.

On cars operating constantly in areas of 75° ambient temperature or over, install the accelerating pump operating rod in the No. 1 hole in the over-travel lever.

21. **Check And Adjust Engine Idle Speed.** Final engine idle speed may be varied to suit the conditions under which the car is to be operated. On a car with an air conditioner, operate the air conditioner for 20 minutes before setting the engine idle speed. Adjust the engine idle speed with the air conditioner operating.

Be sure the parking brake is on. Place the transmission selector lever in drive range position. Check the engine idle speed and adjust it to drive range specifications (450-475 rpm). Place the selector lever in neutral, accelerate the engine and let it return to idle. Place the selector lever in drive range and check the engine idle speed.

After the hot engine idle speed has been adjusted, adjust the fast idle speed by aligning the step of the fast idle cam with the fast idle screw (Fig. 19). With the fast idle screw resting on the step, turn the screw in to obtain 1700 rpm.
22. Check And Adjust Idle Fuel Mixture (Refer to Fig. 20). Make the initial mixture adjustment by turning the needles in until they lightly touch the seat, then back them off 1-1\(\frac{1}{2}\) turns. Do not turn a needle against the seat tight enough to groove the point. If a needle is damaged, it must be replaced before a proper mixture adjustment can be obtained.

Turn the mixture needles in until the engine begins to run rough from the lean mixture. Turn the needles out until the engine begins to "roll" from the rich mixture. Then turn the needles in until the engine runs smoothly. Always favor a slightly rich mixture rather than a lean mixture.

Check the engine idle speed.

23. Check And Adjust Anti-Stall Dashpot Clearance. Loosen the anti-stall dashpot lock nut (Fig. 18).

Hold the throttle in the closed position and depress the plunger with a screw driver blade. Turn the dashpot in its bracket in a direction to provide a clearance of 0.060-0.090 inch between the plunger and the throttle lever. Tighten the lock nut after the adjustment is made.

**ADDITIONAL TESTS AND ADJUSTMENTS**

**CAMSHAFT LOBE LIFT**

1. Remove the air cleaner and the valve rocker arm cover. Remove the valve rocker arm shaft assembly and install a solid tappet-type push rod in the push rod bore of the camshaft lobe to be checked.

2. Make sure the push rod is in the lifter push rod cup. Install a dial indicator in such a manner as to have the actuating point of the indicator in the push rod socket and in the same plane as the push rod movement (Fig. 21).

3. Turn the crankshaft damper slowly in the direction of rotation until the lifter is on the base circle of the camshaft lobe. At this point, the push rod will be in its lowest position.

4. Zero the dial indicator.

5. Continue to rotate the damper slowly until the push rod is in the fully raised position.

6. Compare the total lift recorded on the indicator with specifications.

7. To check on the accuracy of the original indicator reading, continue to rotate the crankshaft until the indicator reads zero.

8. Remove the dial indicator.

9. Install the valve rocker arm shaft. Install the rocker arm cover and the air cleaner.

**VALVE CLEARANCE**

A 0.060-inch shorter push rod (color coded white) or a 0.060-inch longer push rod (color coded yellow) are available for service to provide a means of compensating for dimensional changes in the valve mechanism. Valve stem to valve rocker arm clearance should be 0.078-0.218 inch with the hydraulic lifter completely collapsed. Repeated valve reconditioning operations (valve and/or valve seat refacing) will decrease this clearance to the point that if not compensated for, the hydraulic valve lifter will cease to function.

To determine whether a shorter or a longer push rod is necessary, make the following check:

1. Position the crankshaft as outlined in steps 5 and 6.

2. Position the hydraulic lifter compressor tool on the rocker arm and slowly apply pressure to bleed down the hydraulic lifter until the plunger is completely bottomed (Fig.

22). Hold the lifter in the fully collapsed position.

3. Insert the correct end of the clearance gauge between the valve stem and the rocker arm of the valve being checked.

4. If the first step of the gauge enters, a standard length push rod may be used.

If the first step of the gauge does not enter, replace the standard push rod with a 0.060-inch shorter service push rod.

If the second step of the gauge enters, the operating range of the lifter is excessive. This indicates that the incorrect push rod has been installed or severe wear has occurred at the push rod ends, rocker arm, or valve stem. In this case, it will be necessary to determine the area of discrepancy and the incorrect or defective part(s) should be replaced.

If all the valve train components except the push rod are within limits, install a 0.060-inch longer push rod.

5. Rotate the crankshaft until No. 1 piston is on TDC at the end of the compression stroke. With No. 1 piston on TDC, check the following valves:

- No. 1 Intake
- No. 1 Exhaust
- No. 3 Intake
- No. 4 Exhaust
- No. 7 Intake
- No. 5 Exhaust
- No. 8 Intake
- No. 8 Exhaust

6. Position No. 6 piston on TDC and check the following valves:

- No. 2 Intake
- No. 2 Exhaust
- No. 4 Intake
- No. 3 Exhaust
- No. 5 Intake
- No. 6 Exhaust
- No. 6 Intake
- No. 7 Exhaust

When compressing the valve spring to remove push rods, be sure the piston in the individual cylinder is below
TDC to avoid contact between the valve and the piston.

To replace a push rod, it will be necessary to remove the valve rocker arm shaft assembly. Upon replacement of a valve push rod and/or valve rocker arm shaft assembly, the engine should not be cranked or rotated until the hydraulic lifters have had an opportunity to leak down to their normal operating position. The leak-down rate can be accelerated by using the tool shown in Fig. 22 on the valve rocker arm and applying pressure in a direction to collapse the lifter.

MANIFOLD VACUUM TEST

A manifold vacuum test aids in determining the condition of an engine and also in helping to locate the cause of poor engine performance. To test manifold vacuum:

1. Operate the engine for a minimum of 30 minutes at 1200 rpm.

2. Install an accurate, sensitive vacuum gauge in the fitting in the intake manifold.

3. Operate the engine at recommended idle rpm, with the transmission selector lever in neutral.

4. Check the vacuum reading on the gauge.

TEST CONCLUSIONS

Manifold vacuum is affected by carburetor adjustment, valve timing, the condition of the valves, cylinder compression, and leakage of the manifold, carburetor, or cylinder head gaskets.

Because abnormal gauge readings may indicate that more than one of the above factors is at fault, exercise caution in analyzing an abnormal reading. For example, if the vacuum is low, the correction of one item may increase the vacuum enough to indicate that the trouble has been corrected. It is important, therefore, that each cause of an abnormal reading be investigated and further tests conducted where necessary in order to arrive at the correct diagnosis of the trouble.

Table 2 lists various types of readings and their possible causes.

Allowance should be made for the effect of altitude on the gauge reading. The engine vacuum will decrease with an increase in altitude.

4 ENGINE REMOVAL AND INSTALLATION

The procedures given are for the engine without the transmission attached. If the engine and transmission are removed as an assembly, install standard eye bolts with ½-14 threads in the bosses at the top rear of the exhaust manifolds. Then attach the engine lifting bracket and sling to the eye bolts. The engine installation is shown in Fig. 23.

REMOVAL

1. Drain the cooling system and the crankcase. Remove the hood and the air cleaner.

2. Disconnect the radiator upper hose at the radiator supply tank and the radiator lower hose at the water pump.

3. Disconnect the transmission oil cooler lines at the radiator. Remove the radiator and support as an assembly.

4. Disconnect the battery ground cable at the generator mounting bracket. Remove the oil level dipstick and the ignition coil.

5. Disconnect the oil pressure sending unit wire at the sending unit and the flexible fuel line at the fuel tank line.

6. Remove the wire loom from the clips on the left valve rocker arm cover and position the wires out of the way.

7. Disconnect the three windshield washer lines at the washer pump and position them out of the way.

8. Disconnect the accelerator rod at the carburetor. Remove the accelerator retracting spring. Remove the accelerator cross shaft bracket from the intake manifold and position it out of the way.

9. Disconnect the power steering pump bracket from the water pump, then wire the power steering pump to the hood left hinge in a position that will prevent the oil from draining out.

10. Disconnect the power brake line at the intake manifold and at the flexible line. Release the line from the
brackets on the left valve rocker arm cover and remove the line.

On a car with an air conditioner, disconnect the magnetic clutch wire. Isolate the compressor.

11. Disconnect the heater hose at the water pump and at the intake manifold.

12. Disconnect the generator wires at the generator.

13. Disconnect the water temperature sending unit wire at the sending unit.

14. Remove the engine ground strap and the starter cable retaining bracket from the generator mounting bracket.

15. Raise the front of the car.

16. Remove the starter and dust seal and the transmission fluid filler tube bracket.

17. Disconnect the muffler inlet pipes from the exhaust manifolds, and the engine right and left support insulators at the engine.

18. Remove the converter housing lower access cover and the cover assembly. Remove the flywheel to converter nuts. Secure the converter assembly in the housing. Remove the converter housing to engine lower bolts, and remove the oil cooler lines retaining clamp from the engine block.

19. Lower the car, then support the transmission. Remove the converter housing upper retaining bolts.

20. Install the engine left lifting bracket on the front of the left cylinder head where the coil mounts. Install the engine right lifting bracket at the rear of the right cylinder head. Attach the engine lifting sling (Fig. 24).

21. Raise the engine slightly and carefully pull it from the transmission.

22. Lift the engine out of the engine compartment and install it on a work stand (Fig. 25).

INSTALLATION

1. Position the exhaust gas control valve, with a new gasket on each side, on the right exhaust manifold studs. Temporarily tie the valve to the manifold. Place a new gasket over the studs of the left exhaust manifold.

2. Attach the engine lifting brackets and sling (Fig. 24). Remove the engine from the work stand.

3. Lower the engine carefully into the engine compartment. Make sure the exhaust manifolds are properly aligned with the muffler inlet pipes and the dowels in the block engage the holes in the converter housing. Start the converter pilot into the crankshaft.

4. Install the converter housing upper bolts. Torque the bolts to specifications.

5. Start the engine right and left support insulator to engine bolts. Disconnect the engine lifting sling and remove the lifting brackets.

6. Raise the front of the car. Install the converter housing lower retaining bolts. Torque the bolts to specifications.

7. Remove the retainer securing the converter in the housing. Install the flywheel to converter lockwashers and nuts. Torque the nuts to specifications. Install the converter lower access plate and the housing cover assembly. Install the oil cooler lines retaining clamp.

8. Torque the engine front support insulator bolts to 45-50 ft-lbs torque.

9. Remove the retainer securing the exhaust gas control valve. Connect both exhaust manifolds to the muffler inlet pipes. Torque the nuts to specifications.

10. Position the dust seal and in-
install the starter and the transmission fluid filler tube bracket.

11. Remove the support from the transmission and lower the car.

12. Connect the generator wires.

13. Connect the water temperature sending unit wire. Connect the heater hose at the intake manifold.

14. Connect the engine ground strap and install the starter cable retaining clamp.

15. Connect the flexible fuel line, the oil pressure sending unit wire, and the windshield wiper vacuum line.

16. Install the ignition coil and connect the coil primary and high tension wires.

17. Install the oil level dipstick.

18. Position the wire loom in the retaining clips on the left valve rocker arm cover.

19. Connect the windshield washer pump lines.

20. Install the accelerator cross shaft bracket and the accelerator retracting spring. Connect the accelerator rod.

21. Connect the power steering pump bracket to the water pump.

22. Connect the power brake line to the intake manifold and to the flexible line. Install the line in the retaining clips on the left valve rocker arm cover.

On a car with an air conditioner, connect the magnetic clutch wire and the compressor lines.

23. Install the radiator and support as an assembly. Connect the radiator upper and lower hoses. Connect the transmission oil cooler lines.

24. Fill and bleed the cooling system. Connect the heater hose at the water pump.

25. Fill the crankcase with the proper grade and quantity of engine oil.

26. Operate the engine at fast idle and check all gaskets and hose connections for leaks.

27. Adjust the transmission control linkage. Install the air cleaner.

28. Install and adjust the hood.

5 IN-CHASSIS REPAIR OPERATIONS

ENGINE SUPPORTS

The front supports are located on each side of the crankcase and the rear support is located at the transmission extension housing.

ENGINE FRONT SUPPORT

The engine front support is shown in Fig. 26. The procedures given apply to either a right or left installation.

Removal

1. Remove the insulator assembly to engine retaining bolts, and insulator to underbody retaining nut.

If only one support is being removed, loosen the other support.

2. Raise the engine about 1 inch with a jack and a block of wood placed under the oil pan, then remove the insulator assembly.

Installation

1. Position the insulator assembly. Install, but do not tighten, the insulator to engine lockwashers and bolts. If both supports have been removed, install the bolts on the opposite side before proceeding with step 2.

2. Lower the engine, then install the underbody to insulator nut. Torque the nut to 45-50 ft-lbs. Torque the insulator to engine bolts to 45-50 ft-lbs.

ENGINE REAR SUPPORT

The engine rear support is shown in Fig. 27.

Removal

1. Remove the support retainer bolts and washers and remove the retainer.

2. Raise the extension housing slightly to relieve the pressure on the support assembly. Remove the support assembly.

Installation. Raise the extension housing enough to position the support assembly and retainer. Install the support retainer to extension housing washers and bolts. Torque the support retainer bolts to 45-50 ft-lbs.

VALVE ROCKER ARM SHAFT ASSEMBLY

REMOVAL

1. Operate the engine until normal operating temperature has been reached. Remove the air cleaner.

2. Disconnect the spark plug wires at the spark plugs. Remove the wires from the bracket on the valve rocker arm cover(s) and position the wires out of the way.

To remove the right valve rocker arm cover, remove the carburetor choke heat tube.
To remove the left valve rocker arm cover, disconnect the brake booster line and position the line out of the way.

3. Remove the valve rocker arm cover(s).

If the left cover is removed, position the wire loom out of the way.

4. Crank the engine until the No. 1 piston is at TDC, at the end of the compression stroke. Rotate the crankshaft damper an additional 45° (identified by "XX" on the damper).

5. Starting at the No. 4 cylinder, loosen the right valve rocker arm shaft support bolts in sequence, two turns at a time. After the bolts are all loosened, remove the valve rocker arm shaft assembly and the oil baffle plate. Starting at the No. 5 cylinder, follow the same procedure on the left valve rocker arm shaft support bolts. This procedure must be followed to avoid damage to the valve mechanism.

INSTALLATION

1. Apply Lubriplate to the pad end of the rocker arms, to the tip of the valve stems, and to both ends of the push rods.

2. Crank the engine until the No. 1 piston is on TDC at the end of the compression stroke.

3. Rotate the crankshaft damper an additional 45° (identified by "XX" on the damper).

4. Position the baffle plate and the valve rocker arm shaft assembly on the cylinder heads with the valve push rods in place and the rocker shaft support bolts finger-tight. Be sure the shaft is turned so that the oil holes are to the bottom.

5. Starting at the No. 4 cylinder, tighten the bolts in sequence, two turns at a time, until the supports fully contact the cylinder head. Torque the bolts in sequence to 40-45 ft-lbs.

6. Starting at the No. 5 cylinder, follow the same procedure for the left valve rocker arm shaft support bolts. The additional time consumed in this procedure will permit the hydraulic lifters to leak down. This will minimize the possibility of bending the push rods, valves, or the rocker arms. Be sure that the hydraulic lifters have leak down to their normal operating position before cranking the engine. This is necessary in order to avoid possible damage to the valves, push rods, or valve rocker arms.

7. Clean the valve rocker arm cover(s). Apply oil resistant sealer to one side of the new cover gasket(s). Lay the cemented side of the gasket(s) in place in the cover(s).

8. Position the cover(s) on the cylinder head(s). Make sure the gasket seats evenly all around the head. Install the bolts (and the wire loom clamps on the left cover). The cover is tightened in two steps. First, torque the bolts to 4-7 ft-lbs. Two minutes later, torque the bolts to the same specifications.

9. Connect the spark plug wires. Install the air cleaner.

DISASSEMBLY

1. Remove the cotter pins from each end of the valve rocker arm shaft. Remove the flat washer and spring washer from each end of the shaft.

2. Slide the rocker arms, springs, and the supports off the shaft. Be sure to identify all the parts.

3. If it is necessary to remove the plugs from each end of the shaft, drill or pierce one plug. Insert a steel rod through the plug and knock out the plug on the opposite end. Working from the open end, knock out the remaining plug.

ASSEMBLY

1. Oil all the moving parts with engine oil. Apply Lubriplate to the pad of the valve rocker arms.

2. If the plugs were removed from the ends of the shaft, use a blunt tool or large diameter pin punch and install a plug, cup side out, in each end of the rocker arm shaft.

3. Install the rocker arms, supports, and springs in the order shown.

FIG. 28—Valve Rocker Arm Shaft Assembly
in Fig. 28. Be sure the oil holes in the shaft are facing downward. Complete the assembly by installing the remaining flat washer and the spring washer and install the cotter pin.

**CLEANING AND INSPECTION**

Clean all the parts thoroughly. Make sure that all oil passages are open.
Check the clearance between each rocker arm and the shaft by checking the ID of the rocker arm bore and the OD of the shaft. If the clearance exceeds the wear limit, replace the shaft and/or the rocker arm. Inspect the shaft and the rocker arm bore for nicks, scratches, scores, or scuffs. Dress up minor surface defects with a hone.
Inspect the pad at the valve end of the rocker arms for a grooved radius. If the pad is grooved, replace the rocker arm. **Do not attempt to true this surface by grinding**.
Check for broken locating springs.

**INTAKE MANIFOLD**

**REMOVAL**

1. Operate the engine until normal operating temperature has been reached. Drain the cooling system. Remove the air cleaner.
2. Disconnect the accelerator rod at the carburetor. Remove the accelerator cross shaft bracket from the intake manifold and position it out of the way.
3. Remove the carburetor fuel inlet line and the automatic choke heat tube. Disconnect the brake vacuum booster line at the intake manifold and at the flexible hose. Remove the vacuum line.
4. Disconnect the coil high tension lead, and the coil wires at the coil. Disconnect the oil pressure sending unit wire at the sending unit. Remove the wire loom from the retaining clips on the left valve rocker arm cover and position it out of the way.
5. Disconnect the spark plug wires at the spark plugs and remove the wires from the ignition harness brackets on the valve rocker arm covers.
6. Remove the distributor cap and spark plug wire assembly. Disconnect the distributor vacuum line at the distributor.
7. Remove the distributor hold-down bolt and clamp. Remove the distributor.
8. Disconnect the radiator upper hose at the radiator supply tank, then remove the supply tank. Remove the heater hose at the intake manifold, and the water temperature sending unit wire at the sending unit.
9. Slide the clamp on the water pump by-pass hose toward the water pump.
10. Clean the outside of the valve rocker arm covers and remove the covers.
11. Refer to "Valve Rocker Arm Shaft Assembly Removal" (page 1-19) and remove the valve rocker arm shaft assembly by following steps 4 and 5.
12. Remove the valve push rods in sequence.
13. Remove the intake manifold retaining bolts.
14. Install standard eye bolts with %\(\frac{1}{4}\)-18 threads in the left front and right rear rocker arm cover screw holes. Attach the engine lifting sling (Fig. 29).
15. Raise the manifold and carefully remove the intake manifold and radiator supply tank as an assembly. Remove the intake manifold gaskets and seals.
16. If the manifold is to be disassembled, remove the radiator supply tank, thermostat, and gasket. Remove the carburetor, spacer, and gasket. Remove the crankcase ventilation regulator valve and exhaust tube.

**INSTALLATION**

The intake manifold assembly is shown in Fig. 30.
1. If the intake manifold was disassembled, install the carburetor, spacer, and gasket. Coat the thermostat gasket with water resistant sealer and place it in position on the intake
1. Remove the air cleaner. Disconnect the exhaust manifold at the muffler inlet pipe.
2. Remove the automatic choke heat tube from the right exhaust manifold.
3. Disconnect the power steering pump bracket from the cylinder block and move it out of the way. Position the pump so that the oil will not drain out. Disconnect the power steering hose bracket and position the hoses out of the way.
4. Remove the dipstick and tube assembly.
5. Remove the retaining bolts and tab washers and remove the exhaust manifolds (and the exhaust gas control valve with the right exhaust manifold).

INSTALLATION
1. Clean the mating surfaces of the exhaust manifold and cylinder head. Scrape the gasket material from the mounting flange of the exhaust manifold and muffler inlet pipe.
2. Apply graphite grease to the mating surface of the exhaust manifold.
3. Slide the exhaust gas control valve over the studs of the right exhaust manifold with a new gasket on each side of the control valve.
4. Position the exhaust manifold on the cylinder head and install the retaining bolts and tab washers. Torque the retaining bolts to 23-28 ft-lbs, working from the center to the ends. Lock the bolts by bending one tab of the washer over a flat on the bolt.
5. Install the dipstick and tube assembly.
6. Position the power steering pump bracket on the cylinder block and install the retaining bolts. Adjust the belt tension. Position the hoses and install the power steering hose bracket.
7. Install the automatic choke heat tube on the right exhaust manifold.
8. Connect the exhaust manifold at the muffler inlet pipe. Install the air cleaner.

CLEANING AND INSPECTION

Inspect the manifolds for cracks, leaks, or other defects that would make them unfit for further service.

On the right exhaust manifold, clean out the automatic choke air heat chamber (Fig. 6). Make sure the air inlet and outlet holes are completely open and the cover does not leak. Blow out the automatic choke air heat tube with compressed air.

REGULATOR VALVE—POSITIVE CRANKCASE VENTILATION SYSTEM

REMOVAL

1. Disconnect the exhaust tube clamp from the intake manifold. Disconnect the exhaust tube from the crankcase ventilation outlet and from the intake manifold (Fig. 32).

2. Remove the regulator valve assembly from the exhaust tube.

INSTALLATION

1. Install the regulator valve on the exhaust tube.

3. Install the assembly on the engine. Connect the clamp to the intake manifold.

REGULATOR VALVE DISASSEMBLY

Place the hex on the regulator valve body in a vise. Remove the connector, valve, and spring (Fig. 33).

CLEANING

Clean the valve parts and exhaust tube in clean carburetor solvent and dry them with compressed air. Clean the rubber hose connections with a low volatility petroleum base solvent and dry with compressed air.

REGULATOR VALVE ASSEMBLY

Position the spring and valve inside the regulator valve body. Install the regulator valve connector.

CYLINDER HEADS AND VALVES

CYLINDER HEAD REMOVAL

1. Remove the intake manifold, carburetor, and radiator supply tank as an assembly following the procedure under “Intake Manifold Removal” (page 1-21).

2. Disconnect the exhaust manifolds at the muffler inlet pipes.

If the left cylinder head is to be removed, remove the ignition coil.

3. Remove the cylinder head bolts. Install the cylinder head holding fixtures (Fig. 34).

4. Lift the cylinder heads off the block. Do not pry between the head and the block. Remove and discard the cylinder head gasket.

CYLINDER HEAD INSTALLATION

1. Clean the cylinder head and cylinder block gasket surfaces.

2. If the cylinder head was removed for a cylinder head gasket replacement, check the flatness of the cylinder head and block gasket surfaces.

3. Apply cylinder head gasket sealer to both sides of a new gasket. Guided by the word “FRONT” on the gasket, install the gasket over the cylinder head dowels.

4. Place the cylinder head on the engine, then remove the holding fixture.
5. Install the cylinder head bolts. The cylinder head bolts are tightened in three progressive steps. Torque all the bolts in sequence (Fig. 35) to 70 ft-lbs, then torque them to 80 ft-lbs. Finally, torque them to 90 ft-lbs. After the cylinder head bolts have been torqued to specifications, the bolts should not be disturbed.

6. Connect the exhaust manifolds to the muffler inlet pipes.

7. Install the intake manifold and related parts following the procedure under “Intake Manifold Installation” (page 1-21).

**CYLINDER HEAD DISASSEMBLY**

1. Install the cylinder head holding fixtures (Fig. 34). Remove the deposits from the cylinder head combustion chambers and valve heads with a scraper and a wire brush before removing the valves. Be careful not to scratch the cylinder head gasket surface.

2. Compress the valve spring (Fig. 36). Remove the valve retainer locks and release the spring.

3. Remove the sleeve, spring retainer, spring, damper spring, stem seal, and valve. Discard the valve stem seals. Identify all valve parts.

**CYLINDER HEAD CLEANING**

After the valves are removed, clean the valve guide bores with a valve guide cleaning tool. Use cleaning solvent to remove dirt, grease, and other deposits.

**CYLINDER HEAD INSPECTION**

Check the cylinder head for cracks, and the gasket surface for burrs and nicks. Replace the head if it is cracked. Do not plane or grind more than 0.010 inch from the cylinder head gasket surface. Remove all burrs or scratches with an oil stone.

**Cylinder Head Flatness.** Check the flatness of the cylinder head gasket surface (Fig. 37).

**FIG. 37—Cylinder Head Flatness**

Valve Seat Runout. Check the valve seat runout with an accurate gauge (Fig. 38). Follow the instructions of the gauge manufacturer. If the runout exceeds the wear limit, reface the valve and valve seat.

Valve Seat Width. Measure the valve seat width (Fig. 39).

Reaming Valve Guides. If it be-
sion tight fit. Be sure that the refacer grinding wheels are properly dressed.

Grind the exhaust valve seats to a true 45° angle (Fig. 41). Remove only enough stock to clean up pits, grooves, or to correct the valve seat runout. After the seat has been refaced, measure the seat width (Fig. 39). Narrow the seat, if necessary, to bring it within limits.

If the valve seat width exceeds the maximum limit, remove enough stock from the top edge and/or bottom edge of the seat to reduce the width to specifications (Fig. 41).

Use a 60° angle grinding wheel to remove stock from the bottom of the seat (raise the seat) and use a 30° angle wheel to remove stock from the top of the seat (lower the seat).

The finished valve seat should contact the approximate center of the valve face. It is good practice to determine where the valve seat contacts the face. To do this, coat the seat with Prussian blue, then set the valve in place. Rotate the valve with light pressure. If the blue is transferred to the center of the valve face, the contact is satisfactory. If the blue is transferred to the top edge of the valve face, lower the valve seat. If the blue is transferred to the bottom edge of the valve face, raise the valve seat.

VALVES

Cleaning. Remove all deposits from the valve with a fine wire brush or buffing wheel.

INSPECTION

The critical inspection points and tolerances of the valves are illustrated in Fig. 42.

Inspect the valve face and the edge of the valve head for pits, grooves, scores, or other defects. Inspect the stem for a bent condition and the end of the stem for grooves or scores. Check the valve head for signs of burning, erosion, warpage, and cracking. Defects, such as minor pits, grooves, etc., may be removed. Discard valves that are severely damaged.

Inspect the valve springs, valve spring retainers, locks, and sleeves for defects. Discard any visually defective parts.

Valve Face Runout. Check the valve face runout (Fig. 43). It should not exceed the wear limit.

Valve Stem Clearance. Check the valve stem to valve guide clearance of each valve in its respective valve guide with the tool shown in Fig. 44 or its equivalent. Use a flat-end indicator point.

Valve Spring Pressure. Check the spring for proper pressure (Fig. 45). Do not remove the damper spring when checking the pressure. Weak valve springs cause poor engine performance; therefore, if the pressure of any spring exceeds the wear limit, replace the spring.

Valve Spring Squareness. Check each spring for squareness, using a steel square and a surface plate (Fig. 46). Stand the spring and square on end on the surface plate. Slide the spring up to the square. Revolve the spring slowly and observe the space between the top coil of the spring and the square. If the spring is out of square more than 1/16 inch, replace it.
Valve Push Rods. Check the ends of the push rods for nicks, grooves, roughness, or excessive wear.

The push rods can be visually checked for straightness while they are installed in the engine by rotating them with the valve closed. They also can be checked with a dial indicator (Fig. 47). If the runout exceeds the maximum limit at any point, discard the rod. Do not attempt to straighten push rods.

Refacing Valves. The valve refacing operation should be closely coordinated with the valve seat refacing operation so that the finished angle of the valve face will match the valve seat. This is important so that the valve and seat will have a good compression tight fit. Be sure that the refacer grinding wheels are properly dressed.

![Dial Indicator](image)

**FIG. 47—Push Rod Runout**

If the valve face runout is excessive and/or to remove pits and grooves, reface the valves to a true 44° angle. Remove only enough stock to correct the runout or to clean up the pits and grooves. If the edge of the valve head is less than 1/32 inch after grinding, replace the valve as the valve will run too hot in the engine.

Remove all grooves or score marks from the end of the valve stem, then chamfer as necessary. Do not remove more than 0.010 inch from the stem.

After refacing the valves, it is good practice to lightly lap the valves with a medium grade lapping compound to match the seats. Be sure to remove all the compound from the valve and seat after the lapping operation.

Select Fitting Valves. If the valve stem to valve guide clearance exceeds the wear limit, ream the valve guide for the next oversize valve stem. Valves with oversize stem diameters of 0.003, 0.015, and 0.030 inch are available for service. Always reface the valve seat after the valve guide has been reamed.

**CYLINDER HEAD ASSEMBLY**

1. Install each valve (Fig. 48) in the port from which it was removed or to which it was fitted. Install a new stem seal on the valve.

2. Install the valve springs over the valve, and then install the spring retainer and sleeve. Make sure the valve damper spring is installed in the valve spring so that the coil end of the damper spring is 135° counterclockwise from the coil end of the valve spring.

3. Compress the spring and install the retainer locks (Fig. 36).

![Valve Assembly](image)

**FIG. 48—Valve Assembly**

4. Measure the assembled height of the valve spring from the surface of the cylinder head spring pad to the underside of the spring retainer with dividers (Fig. 49). Check the dividers against a scale. If the assembled height is greater than 1 1/4 inches, install the necessary 0.030-inch thick spacer(s) between the cylinder head spring pad and the valve spring to bring the assembled height to the recommended height of 1 7/16 inches. Do not install spacers unless necessary. Use of spacers in excess of recommendations will result in over stressing the valve springs and overloading the camshaft lobes which could lead to spring breakage and worn camshaft lobes.

**VALVE STEM SEAL REPLACEMENT**

1. Remove the air cleaner and the valve rocker arm cover. Remove the applicable spark plug.

2. Crank the engine until the applicable piston is on TDC after the compression stroke. Be sure that both valves are closed. Be sure that the piston is on TDC to prevent the crankshaft from turning when the air is applied.

3. Install an air line with an adapter in the spark plug hole and turn on the air supply.

4. Position the hydraulic lifter compressor tool on the applicable rocker arm and slowly apply pressure to bleed down the hydraulic lifter until the plunger is completely bottomed (Fig. 50). Remove the push rod.

5. Push the rocker arm to one side and secure it in this position.

![Valve Spring Assembled Height](image)

**FIG. 49—Valve Spring Assembled Height**

**FIG. 50—Bleeding Down Hydraulic Valve Lifter**

---

**Tool—T58P-6565-A-1**
installed in the valve spring so that the coil end of the damper spring is 135° counterclockwise from the coil end of the valve spring.

8. Apply Lubriplate to both ends of the push rod. Install the push rod making sure the lower end of the rod is positioned in the lifter push rod cup.

9. Remove the wire securing the valve rocker arm and slide the rocker arm into position. Turn off the air and remove the air line and adapter. Install the spark plug.

10. Install the valve rocker arm cover and connect the spark plug wires. Install the air cleaner.

**CYLINDER FRONT COVER AND TIMING CHAIN REMOVAL**

1. Drain the cooling system and the crankcase. Remove the air cleaner. Disconnect the battery ground cable.

2. Disconnect the radiator upper hose at the radiator supply tank. Disconnect the radiator lower hose at the water pump.

3. Disconnect the transmission oil cooler lines at the radiator. Remove the radiator and support as an assembly.

4. Disconnect the heater hose at the water pump. Slide the water pump by-pass hose clamp toward the engine.

5. Disconnect the power steering pump bracket from the water pump and remove the drive belt. Wire the power steering pump assembly to the left side of the car in a position that will prevent the oil from draining out.

On a car with an air conditioner, remove the compressor drive belt.

6. Loosen the generator mounting bolts at the generator. Remove the drive belt. Remove the generator support bolt at the water pump. Remove the water pump, drive belt adjusting arm, pulley, and fan as an assembly. Remove the power steering pulley from the crankshaft damper.

7. Remove the cap screw and washer from the end of the crankshaft. Install the puller on the crankshaft damper (Fig. 53) and remove the damper.

8. Disconnect the carburetor fuel inlet line at the fuel pump.

9. Remove the fuel pump retaining bolts and lay the pump to one side with the flexible fuel line still attached.

10. If the crankshaft sleeve is not stepped down (the same OD on both ends), remove it as shown in Fig. 54. If the sleeve is stepped down, remove it with a three jawed puller (tool 7675-N).

11. Remove the screws fastening the cylinder front cover to the block. Remove the cylinder front cover. On a car with an air conditioner, the compressor brackets are retained by cylinder front cover screws.

12. Discard the cylinder front cover gasket. Remove the oil slinger.

13. Rotate the crankshaft in a clockwise direction (as viewed from the front) to take up the slack on the left side of the chain.

14. Establish a reference point on the block and measure from this point to the chain (Fig. 55).

15. Rotate the crankshaft in the opposite direction to take up the slack on the right side of the chain. Force the left side of the chain
16. Install the alignment pilot tool on the cylinder front cover so that the keyways in the pilot aligns with the keyway in the pilot aligns with the cover and pilot over the end of the camshaft and against the block (Fig. 59). Install the retaining screws.

17. Remove the camshaft thrust button and spring, the sprocket cap screw, the thrust button spring retainer, and the fuel pump eccentric.

18. Slide both sprockets and the timing chain forward, and remove the sprockets and timing chain as an assembly (Fig. 57).

19. Remove the oil pan and oil pump screen, following the procedure under "Oil Pan Removal" (page 1-36).

INSTALLATION

1. Position the sprockets and timing chain on the camshaft and crankshaft (Fig. 57). Be sure the timing marks on the sprockets are positioned as shown in Fig. 56.

2. Install the fuel pump eccentric, the camshaft sprocket cap screw, and the thrust button spring retainer. Torque the sprocket cap screw to 35-45 ft-lbs. Install the camshaft thrust button spring and thrust button (Fig. 58). Install the crankshaft front oil slinger.

3. Clean the cylinder front cover, oil pan, and the block gasket surfaces.

4. Coat the gasket surface of the block and cover and the cover bolt threads with sealer. Position a new gasket on the block.

5. Install the alignment pilot tool on the cylinder front cover so that the keyways in the pilot aligns with the keyway in the pilot aligns with the cover and pilot over the end of the crankshaft and against the block (Fig. 59). Install the retaining screws.

6. Install the crankshaft sleeve.

7. Line up the damper keyway with the key on the crankshaft. Install the damper on the crankshaft (Fig. 60).

8. Install the damper cap screw and washer, and torque the screw to 70-90 ft-lbs.

9. Install the power steering pump pulley on the damper. Torque the screws to 20-25 ft-lbs.
10. Clean the oil pan and the oil pump screen. Install the oil pump screen and oil pan (Page 1-36).

11. Clean the water pump gasket surfaces. Coat new gaskets with sealer and position the gaskets on the block. Install the water pump, pulley, fan, and generator adjusting arm as an assembly.

12. Install and adjust the generator drive belt(s).

On a car with an air conditioner, install and adjust the drive belt.

13. Install the power steering pump drive belt and attach the pump bracket to the water pump. Adjust the drive belt tension.

15. Connect the carburetor fuel inlet line. Connect the heater hoses. Slide the water pump by-pass tube clamp forward on the tube.

16. Install the radiator and support as an assembly. Connect the radiator lower hose at the water pump and the radiator upper hose at the radiator supply tank. Connect the battery ground cable. Connect the transmission oil cooler lines.

17. Fill and bleed the cooling system. Fill the crankcase with the proper grade and quantity of engine oil. Connect the heater hose to the intake manifold.

18. Operate the engine at fast idle and check for coolant and oil leaks. Adjust the ignition timing. Install the air cleaner.

CLEANING AND INSPECTION

Clean all parts in solvent and dry them with compressed air. Inspect the chain for broken links and the sprockets for cracks, and worn or damaged teeth. Replace all the components of the timing chain and sprocket assembly if any one item needs replacement.

FRONT OIL SEAL REPLACEMENT

It is good practice to replace the oil seal each time the cylinder front cover is removed.

1. Drive out the old seal with a pin punch. Clean out the recess in the cover.

2. Coat a new seal with grease, then install the seal (Fig. 61). Drive the seal in until it is fully seated in the recess. Check the seal after installation to be sure the spring is properly positioned in the seal.

CAMSHAFT

The camshaft and related parts are shown in Fig. 62.

REMOVAL

1. Operate the engine until normal operating temperature has been reached. Remove the cylinder front cover and the timing chain and sprockets following steps 1 thru 18 under "Cylinder Front Cover and Timing Chain Removal" on page 1-27.

2. Disconnect the spark plug wires at the spark plugs and remove the wires from the ignition harness brackets on the valve rocker arm covers. Disconnect the coil high tension lead at the coil. Remove the distributor cap and spark plug wire assembly. Disconnect the distributor vacuum line at the distributor. Remove the distributor hold down bolt and clamp and remove the distributor.

3. Remove the valve rocker arm covers. Refer to "Valve Rocker Arm Shaft Assembly Removal" (page 1-19) and remove the valve rocker arm shaft assemblies by following steps 4 and 5.

4. Remove the valve push rods in sequence and place them in a rack so that they can be installed in their original positions.

5. Position an inspection light through a push rod opening and into the valve push rod valley (Fig. 63). Remove the valve lifters with a magnet through the push rod openings. In some cases, it will be necessary to transfer the lifter over to an adjoining push rod opening in order to remove it. Place the lifters in a rack so that they can be installed in their original positions.

6. Remove the oil pan and oil pump screen by following the pro-
procedure under "Oil Pan Removal" on page 1-36.

7. Carefully remove the camshaft by pulling it toward the front of the engine. Use caution to avoid damaging the camshaft bearings.

INSTALLATION

1. Oil the camshaft and apply Lubriplate to the lobes. Carefully slide the camshaft through the bearings.

2. Position the sprockets and timing chain on the camshaft and crankshaft (Fig. 57) with the timing marks on the sprockets aligned as shown in Fig. 56.

3. Install the oil pump eccentric, the camshaft sprocket cap screw, and thrust button spring retainer. Torque the sprocket cap screw to 35-45 ft-lbs. Install the camshaft thrust button (Fig. 58). Install the front oil slinger.

4. Replace the crankshaft front oil seal (page 1-29). Install the cylinder front cover, the crankshaft damper, and related parts following steps 3 thru 16 under "Cylinder Front Cover and Timing Chain Installation" on page 1-28.

5. With No. 1 piston on TDC at the end of the compression stroke, position the distributor in the block with the rotor at the No. 1 firing position and the points open. Install the hold down clamp.

6. Connect the distributor vacuum line. Install the distributor cap. Connect the coil high tension lead.

7. Install the valve lifters in the bores from which they were removed.

8. Refer to "Valve Rocker Arm Shaft Assembly Installation" on page 1-20 and install the valve rocker arm shaft assembly following steps 1 thru 9.

9. Fill and bleed the cooling system. Fill the crankcase with the proper grade and quantity of engine oil.

10. Start the engine and check and adjust the ignition timing. Operate the engine at fast idle and check all hose connections and gaskets for leaks.

CLEANING AND INSPECTION

Clean the camshaft in solvent and wipe it dry. Inspect the camshaft lobes for scoring, and signs of abnormal wear. Lobe wear characteristics may result in pitting in the general area of the nose portion of the lobe. This pitting is not detrimental to the operation of the camshaft, therefore, the camshaft should not be replaced until the lobe lift loss has exceeded 0.005 inch.

The lift of camshaft lobes can only be accurately checked with the camshaft installed in the engine. Refer to "Camshaft Lobe Lift" on page 1-16.

Check the distributor drive gear for broken or chipped teeth.

Remove light scuffs, scores, or nicks from the camshaft machined surfaces with a smooth oilstone.

CAMSHAFT REAR BEARING BORE PLUG REPLACEMENT

1. Remove the transmission and converter housing by following the procedure in Part 5-4.

2. Remove the flywheel retaining bolts and remove the flywheel.

3. Drill a ½-inch hole in the camshaft rear bearing bore plug and use tool T-7600-E to remove the plug.

4. Clean out the plug bore recess thoroughly.

5. Coat the flange of a new plug with water resistant sealer and install it with the flange facing out (Fig. 91).

6. Install the flywheel.

7. Install the transmission and converter housing by following the procedure in Part 5-4.

HYDRAULIC VALVE LIFTER REPLACEMENT

The following procedure is applicable for removing one or all of the valve lifters. This procedure can not be used if the valve lifters are stuck in their bores by excessive varnish, etc. In this case it will be necessary to remove the intake manifold following the procedure on page 1-21. After the intake manifold has been removed, remove the valve lifters.

1. Refer to "Valve Rocker Arm Shaft Assembly Removal" (page 1-19) and remove the valve rocker arm covers and the valve rocker arm shaft assemblies by following steps 1 thru 5.

2. Position an inspection light through a push rod opening and into the valve push rod valley (Fig. 63). Remove the valve lifters with a magnet through the push rod openings. In some cases, it will be necessary to transfer the lifter over to an adjoining push rod opening in order to re-
move it. Place the lifters in a rack so that they can be installed in their original positions.

The internal parts of each hydraulic valve lifter assembly are matched sets. Do not intermix the parts. Keep the assemblies intact until they are to be cleaned.

3. Install the new (or cleaned) hydraulic valve lifters through the push rod openings with a magnet (Fig. 63).

4. Refer to "Valve Rocker Arm Shaft Assembly Installation" (page 1-20) and install the valve rocker arm shaft assemblies and the covers by following steps 1 thru 9.

CLEANING AND INSPECTION

The lifter assemblies should be kept in proper sequence so that they can be installed in their original position. Inspect and test each lifter separately so as not to intermix the internal parts. If any part of the lifter assembly needs replacing, replace the entire assembly.

Thoroughly clean all the parts in clean solvent and wipe them with a clean, lint-free cloth.

Inspect the parts and discard the entire lifter assembly if any part shows signs of pitting, scoring, galling, or evidence of non-rotation. Replace the entire assembly if the plunger is not free in the body. The plunger should drop to the bottom of the body by its own weight.

Assemble the lifter assembly and check the assembly for freeness of operation by pressing down on the push rod cup. The lifter can also be checked with a hydraulic valve lifter tester to test the leak-down rate. The leak-down rate specification is 10-80 seconds. Follow the instructions of the test unit manufacturer.

DISASSEMBLY

Each valve lifter is a matched assembly. If the parts of one lifter are inter-mixed with those of another, improper valve operation may result. Disassemble and assemble each lifter separately. Keep the lifter assemblies in proper sequence so that they can be installed in their original bores.

1. Grasp the lock ring with needle-nose pliers to release it from the groove. If necessary, depress the plunger to fully release the lock ring.

2. Remove the push rod cup, plunger, and spring.

3. Invert the plunger assembly and remove the disc valve retainer by carefully prying up on it with a screwdriver. Remove the disc valve and spring.

ASSEMBLY

A typical hydraulic valve lifter is shown in Fig. 64.

1. Place the plunger upside down on a clean work bench.

2. Place the disc valve in position over the oil hole on the bottom of the plunger. Set the disc valve spring on top of the disc.

3. Position the disc valve retainer over the disc and spring and push the retainer down into place on the plunger.

4. Place the plunger spring, and then the plunger (open end up) into the lifter body.

5. Place the push rod seat in the plunger.

6. Depress the plunger, and position the closed end of the lock ring in the groove of the lifter body. With the plunger still depressed, position the open ends of the lock ring in the groove. Release the plunger, then depress it again to fully seat the lock ring.

CRANKSHAFT LOWER REAR OIL SEAL REPLACEMENT

The upper oil seal in the block cannot be replaced with the crankshaft installed. To replace the lower rear oil seal in the rear main bearing cap and the side seals:

1. Remove the oil pan and related parts (page 1-36).

2. Remove the rear main bearing cap. Remove and discard the rear seal and side seals.

3. Clean the rear journal oil seal groove.

4. Install a new rear journal oil seal in the rear main bearing cap (Fig. 65). After installation, cut the ends of the seals flush.

5. Apply a thin coating of oil resistant sealer to the rear main bearing cap at the rear of the top mating surface (Fig. 65). Do not apply sealer to the area forward of the side seal groove. Install the rear main bearing cap. Torque the cap bolts to 95-105 ft-lbs.

6. Dip the side seals in light engine oil, then immediately install them in the grooves. Do not use sealer on the side seals. The seals are designed to expand when dipped in oil. Using sealer may retard this expansion. It may be necessary to tap the seals into place for the last ½ inch of travel. Do not cut the seal projecting ends.

7. Check the retainer side seals for leaks by squirting a few drops of oil into the parting lines between the rear main bearing cap and the cylinder block from the outside. Blow compressed air against the seals from the inside of the block. If air bubbles appear in the oil, it indicates possible oil leakage. This test should not be performed on newly installed seals until sufficient time has been allowed for the seals to expand into the seal grooves.

8. Install the oil pan and related parts (page 1-36).

9. Fill the crankcase. Start the engine and check for oil pressure. Operate the engine at fast idle and check for oil leaks.
MAIN AND CONNECTING ROD BEARING REPLACEMENT

The main connecting rod bearing inserts are selective fit. Do not file or lap bearing caps or use shims to obtain the proper bearing clearance.

Selective fit bearings are available for service in standard sizes only. Standard bearings are divided into two sizes and are identified by a daub of red or blue paint. Refer to the Parts Catalog for the available sizes. Red marked bearings increase the clearance; blue marked bearings decrease the clearance. Undersized bearings, which are not selective fit, are available for use on journals that have been refinished.

MAIN BEARING REPLACEMENT

1. Drain the crankcase. Remove the oil level dipstick. Remove the oil pan and oil pump by following the procedures on page 1-36. Remove the spark plugs to allow easy rotation of the crankshaft.

2. Replace one bearing at a time leaving the other bearing securely fastened. Remove the main bearing cap to which new bearings are to be installed.

3. Insert the upper bearing removal tool (tool 6331) in the oil hole in the crankshaft.

4. Rotate the crankshaft in the direction of engine rotation to force the bearing out of the block.

5. Clean the crankshaft journal and bearing inserts. When replacing standard bearings with new bearings, it is good practice to first try to obtain the proper clearance with two blue bearing halves.

6. To install the upper main bearing, place the plain end of the bearing over the shaft on the locking tang side of the block. Using tool 6331 in the oil hole in the crankshaft, rotate the crankshaft in the opposite direction of engine rotation until the bearing seats itself. Remove the tool.

7. Replace the cap bearing.

8. Support the crankshaft so its weight will not compress the Plastigage and provide an erroneous reading. Position a small jack so it will bear against the counterweight adjoining the bearing which is being checked.

9. Place a piece of Plastigage on the bearing surface the full width of the bearing cap and about 1/4 inch off center (Fig. 66).

CONNECTING ROD BEARING REPLACEMENT

1. Follow step 1 under “Main Bearing Replacement.”

2. Turn the crankshaft until the connecting rod to which new bearings are to be fitted is down.

3. Remove the connecting rod cap. Push the connecting rod up into the cylinder and remove the bearing insert from the rod and cap.

4. Follow step 5 under “Main Bearing Replacement.”

5. Install the new bearings in the connecting rod and cap. Pull the connecting rod assembly down firmly on the crankshaft journal.

6. Place a piece of Plastigage on the lower bearing surface, the full width of the cap and about 1/4 inch off center.

7. Install the cap and torque the connecting rod nuts to 40-45 ft-lbs. Do not turn the crankshaft while the Plastigage is in place.

8. Remove the cap. Using the Plastigage scale, check the width of the Plastigage by following step 11 under “Main Bearing Replacement.”

9. After the bearing clearance has been checked and found to be satisfactory, apply a light coat of engine oil to the journal and bearings. Install the connecting rod cap.

10. Repeat the procedure for the remaining connecting rods that require new bearings.

11. Follow steps 14, 15, and 16 under “Main Bearing Replacement.”

CLEANING AND INSPECTION

Clean the bearing inserts and caps thoroughly. Inspect each bearing carefully. Bearings that have a scored, chipped, or worn surface should be replaced. Typical examples of bearing failure and their causes are shown in Fig. 67. Check the clearance of bearings that appear to be satisfactory with Plastigage. Fit new bearings following the recommended procedure. The copper lead bearing base may be visible through the bearing overlay. This does not mean that the bearing is worn. Do not replace the bearing if the bearing clearance is within recommended limits.

PISTON AND CONNECTING ROD ASSEMBLY

REMOVAL

1. Drain the cooling system and the crankcase. Remove the intake
FIG. 67—Typical Bearing Failures

manifold, cylinder heads, oil pan and oil pump following the procedures in this section.

2. Remove any ridge and/or deposits from the upper end of the cylinder bores as follows:

Turn the crankshaft until the piston to be removed is at the bottom of its travel and place a cloth on the piston head to collect the cuttings. Remove any ridge and/or deposits from the upper end of the cylinder bores. Remove the cylinder ridge with a ridge cutter. Follow the instructions furnished by the tool manufacturer. Never cut into the ring travel area in excess of 1/32 inch when removing ridges.

3. Make sure all connecting rod caps are marked so that they can be installed in their original locations.

4. Turn the crankshaft until the connecting rod being removed is down.

5. Remove the connecting rod cap.

6. Push the connecting rod and piston assembly out the top of the cylinder with the handle end of a hammer. Avoid damage to the crankshaft journal or the cylinder wall when removing the piston and rod.

7. Remove the bearing inserts from the connecting rod and cap.

8. Install the cap on the connecting rod from which it was removed.

INSTALLATION

1. If new piston rings are to be installed, remove the cylinder wall glaze. Follow the instructions of the tool manufacturer.

2. Oil the piston rings, pistons, and cylinder walls with light engine oil. Be sure to install the pistons in the same cylinders from which they were removed, or to which they were fitted. The connected rods and bearing caps are numbered from 1 to 4 in the right bank and from 5 to 8 in the left bank beginning at the front of the engine. The numbers on the connecting rod and bearing cap must be on the same side when installed in the cylinder bore. If a connecting rod is ever transposed from one block or cylinder to another, new bearings should be fitted and the connecting rod should be numbered to correspond with the new cylinder number.

3. Make sure the ring gaps are properly spaced around the circumference of the piston.

4. Install a piston ring compressor on the piston and push the piston in with a hammer handle until it is slightly below the top of the cylinder (Fig. 68). Be sure to guide the connecting rods to avoid damaging the crankshaft journals. Install the piston with the indentation in the piston head toward the front of the engine.

5. Check the clearance of each bearing by following the procedure under “Connecting Rod Bearing Replacement.”

6. After the bearings have been fitted, apply a light coat of engine oil to the journals and bearings.

7. Turn the crankshaft throw to the bottom of its stroke. Push the piston all the way down until the connecting rod bearing seats on the crankshaft journal.

8. Install the connecting rod cap. Torque the nuts to 40-45 ft-lbs.

9. After the piston and connecting rod assemblies have been installed, check the side clearance between the connecting rods on each crankshaft journal (Fig. 69).

10. Disassemble, clean, and assemble the oil pump (page 1-37). Clean the oil pump inlet tube screen, and the oil pan and block gasket surfaces.

11. Install the oil pump and the oil pan (page 1-36).

12. Install the cylinder heads by following steps 1 thru 5 under “Cylinder Head Installation” on page 1-23.

13. Refer to “Intake Manifold Installation” on page 1-21 and install the intake manifold by following steps 2 thru 19.

14. Fill and bleed the cooling system. Fill the crankcase with the proper grade and quantity of engine oil.

15. Operate the engine and check for oil and coolant leaks. Check and
adjust the ignition timing. Adjust the engine idle speed and fuel mixture.

16. Install the air cleaner.

DISASSEMBLY

1. Mark the pistons and pins to assure assembly with the same rod and installation in the same cylinder from which they were removed.

2. Remove the piston rings. Remove the piston pin retainers. Drive the pin out of the piston and connecting rod (Fig. 70). Discard the retainers.

![Fig. 70—Piston Pin Removal](image)

**FIG. 70—Piston Pin Removal**

4. Be sure the bearing inserts and the bearing bore in the connecting rod and cap are clean. Foreign material under the inserts may distort the bearing and cause a failure. Install the bearing inserts in the connecting rod and cap with the tangs fitting in the slots provided.

**FIG. 71—Piston, Connecting Rod, and Related Parts**

3. Check the ring side clearance of the compression rings with a feeler gauge inserted between the ring and its lower land (step 6 under "Fitting Piston Rings" on page 1-36).

ASSEMBLY

The piston, connecting rod, and related parts are shown in Fig. 71.

1. Lubricate all parts with light engine oil. Position the connecting rod in the piston and push the pin into place. Assemble the piston and connecting rod with the oil squirt hole positioned as shown in Fig. 72.

2. Insert new piston pin retainers by spiraling them into the piston with the fingers. Do not use pliers. Follow the instructions contained on the piston ring package and install the piston rings.

**FIG. 72—Connecting Rod and Piston Assembly**

![Diagram of Connecting Rod and Piston Assembly](image)

3. Check the ring side clearance of the compression rings with a feeler gauge inserted between the ring and its lower land (step 6 under “Fitting Piston Rings” on page 1-36).

4. Be sure the bearing inserts and the bearing bore in the connecting rod and cap are clean. Foreign material under the inserts may distort the bearing and cause a failure. Install the bearing inserts in the connecting rod and cap with the tangs fitting in the slots provided.

CONNECTING ROD CLEANING AND INSPECTION

The connecting rods and related parts should be carefully inspected and checked for conformance to specifications. Various forms of engine wear caused by these parts can be readily identified.

A shiny surface on the pin boss side of the piston usually indicates that a connecting rod is bent or the piston pin hole is not in proper relation to the piston skirt and ring grooves. Abnormal connecting rod bearing wear can be caused by either a bent connecting rod, an improperly machined crankshaft journal, or a tapered connecting rod bore.

Twisted connecting rods will not create an easily identifiable wear pattern, but badly twisted rods will disturb the action of the entire piston, rings, and connecting rod assembly and may be the cause of excessive oil consumption.

Clean the connecting rod in solvent, including the rod bore and the back of the inserts. Do not use a caustic cleaning solution. Blow out all passages with compressed air.

Inspect the connecting rods for signs of fractures and the bearing bores for out-of-round and taper. If the bore exceeds the recommended limits and/or if the connecting rod is fractured, it should be replaced.

Check the piston pin to connecting rod bushing clearance. Replace the connecting rod if the bushing is so worn that it cannot be reamed or honed for an oversize pin.

Replace defective connecting rod nuts and bolts.

After the connecting rods are assembled to the piston, check the connecting rods for bend or twist on a suitable alignment fixture. Follow the instructions of the fixture manufacturer. If the bend and/or twist is excessive, the connecting rod should be straightened or replaced.

PISTONS, PINS, AND RINGS

CLEANING AND INSPECTION

Remove deposits from the piston surfaces. Clean gum or varnish from the piston skirt, piston pins, and rings with solvent. Do not use a caustic cleaning solution or a wire brush to clean pistons. Clean the ring grooves with a ring groove cleaner (Fig. 73). Make sure the oil ring slots (or holes) are clean.

Carefully inspect the pistons for fractures at the ring lands, skirts, and pin bosses, and for scuffed, rough, or scored skirts. If the lower inner portion of the ring grooves have high steps, replace the piston. The step will interfere with ring operation and cause excessive ring side clearance.

![Fig. 73—Cleaning Ring Grooves](image)
FIG. 74—Piston Clearance Chart

Spongy, eroded areas near the edge of the top of the piston are usually caused by detonation, or pre-ignition. A shiny surface on the thrust surface of the piston, offset from the centerline between the piston pin holes, can be caused by a bent connecting rod. Replace pistons that show signs of excessive wear, wavy ring lands, fractures, and/or damage from detonation or pre-ignition.

Check the piston to cylinder bore clearance with a tension scale and ribbon by following the procedure under “Fitting Pistons.” Check the ring side clearance by following the procedure under “Fitting Piston Rings.”

Replace piston pins showing signs of fracture or etching and/or wear. Check the piston pin fit in the piston and rod.

Replace all rings that are scored, chipped, or cracked. It is good practice to always install new rings when overhauling the engine. Rings should not be transferred from one piston to another regardless of mileage.

FITTING PISTONS

Pistons are available for service in standard sizes and 0.020, 0.030, 0.040, and 0.060-inch oversize.

The piston to cylinder bore clearance should be from 0.0017–0.0035 inch. The wear limit is 0.006 inch.

If the clearance is greater than the maximum limit, recheck calculations to be sure that the proper size piston has been selected. Check for a damaged piston, then try a new piston.

If the clearance is less than the minimum limit, recheck calculations before trying another piston. If none can be fitted, refinish the cylinder for the next size piston. When a piston has been fitted, mark it for assembly in the cylinder to which it was fitted.

If the taper and out-of-round conditions of the cylinder bore are within limits, new piston rings will give satisfactory service provided the piston clearance in the cylinder bore is within limits. If the new rings are to be installed in a used cylinder that has not been refinished, remove the cylinder wall “glaze.”

To fit a piston:

1. Calculate the size piston to be used by taking a cylinder bore check (Fig. 94).

2. Select the proper size piston to provide the desired clearance.

3. Make sure the piston and cylinder bore are at room temperature (70°F). After any refinishing operation, allow the cylinder bore to cool and make sure the piston and bore are clean and dry before the piston fit is checked.

4. Attach a tension scale to the end of a feeler gauge ribbon that is free of dents or burrs. The feeler ribbon should be ½-inch wide and of one of the thicknesses shown in Fig. 74.

5. Position the ribbon in the cylinder bore so that it extends the entire length of the piston at 90° from the piston pin location. Invert the piston and install it in the bore so that the end of the piston is about 1½ inches below the top of the cylinder block and the piston pin is parallel to the crankshaft axis. Hold the piston and slowly pull the scale in a straight line with the ribbon, noting the pull required to remove the feeler ribbon (Fig. 75).

In Fig. 74 the diagonal lines represent feeler ribbons of various thicknesses, the horizontal lines represent the pounds pull, and the vertical lines represent the clearances. To determine the clearance, locate the line representing the pounds pull required to remove the feeler ribbon from the cylinder bore. Follow the horizontal line to the right until it intersects the diagonal line representing the feeler ribbon. Read down the vertical line for the clearance.

Example 1. If a 0.0015-inch feeler ribbon is used and it takes approximately 4½ pounds pull to remove the feeler ribbon, the clearance is approximately 0.0008 inch. This is determined by locating the pounds pull (4½) in Fig. 74 and following the line to the right until it intersects with the diagonal line representing the 0.0015-inch feeler ribbon. Read down the vertical line for the clear-
should slide freely around the entire ring circumference without binding. Any wear that occurs will form a step at the inner portion of the lower land. If the lower lands have high steps, the piston should be replaced.

FITTING PISTON PINS

The piston pin fit should be a light thumb press fit at normal temperature (70°F). Standard piston pins are coded green.

Pins of 0.001-inch oversize (color coded blue) and 0.002-inch oversize (color coded yellow) are available.

If the pin hole in the piston must be reamed, use an expansion-type piloted reamer. Place the reamer in a vise and revolve the piston around the reamer. Set the reamer to the size of the pin bore, then expand the reamer slightly and trial ream the pin bore. Take a light cut. Use a pilot sleeve of the nearest size to maintain alignment of the bores.

Check the hole size, using the new piston pin. If the bore is small, expand the reamer slightly and make another cut. Repeat the procedure until the proper fit is obtained. Check the piston pin for fit in the respective rod bushing. If necessary, ream or hone the bushing to fit the pin.

FLYWHEEL

REMOVAL

1. Disconnect the transmission from the engine and slide it to the rear as outlined in Part 5-4.
2. Remove the flywheel retaining bolts and remove the flywheel.

INSTALLATION

1. Install the flywheel on the crankshaft flange and install the retaining bolts. Torque the bolts in sequence across from each other to 75-85 ft-lbs.
2. Connect the transmission to the engine as outlined in Part 5-4.

OIL FILTER REPLACEMENT

1. Place a drip pan under the filter. Unscrew the filter from the adapter fitting. Clean the adapter filter recess.
2. Coat the gasket on the new filter with oil, and place the filter in position on the adapter (Fig. 78). Hand tighten the filter until the gasket contacts the adapter face, then advance it ½ turn.

OIL PAN AND OIL PUMP

REMOVAL

1. Drain the cooling system and the crankcase. Disconnect the radiator upper hose at the radiator supply tank.
2. Remove the oil pan retaining screws and lower the oil pan to the underbody cross member. Position the crankshaft so that the counterweight will clear the oil pan and move the pan forward.
3. Install the engine lifting brackets and sling. Raise the engine high enough to place tension on the engine mounts.
4. Remove the engine front insulator to engine retaining bolts. Raise the engine high enough to permit removal of the oil pump retaining bolts, then remove the bolts. Remove the oil pan and the oil pump.

INSTALLATION

1. Clean the oil pan and block gasket surfaces. Clean the oil pump and inlet tube screen. Position a new
oil pump inlet tube gasket on the oil pump and install the tube. Prime the oil pump by filling either the inlet or outlet port with engine oil. Rotate the pump shaft to distribute the oil within the pump body.

2. Raise the engine high enough to allow installation of the oil pump and the oil pan. Place the oil pump in the oil pan and position the oil pan on the underbody cross member. Insert the oil pump drive shaft into the oil pump housing and install the oil pump and shaft as an assembly. Do not attempt to force the pump into position if it will not seat readily. The drive shaft hex may be misaligned with the distributor shaft. To align, rotate the intermediate shaft into a new position. Tighten the oil pump retaining screws to specifications (Fig. 79).

3. Hold the oil pan in place against the cylinder block and install a retaining screw on each side of the oil pan. Install the remaining screws and tighten them, from the center outward, to specifications.

4. Lower the engine, then install the engine right and left front support retaining bolts. Tighten the bolts to specifications. Remove the engine lifting bracket and sling. Connect the radiator upper hose. Fill the cooling system. Fill the crankcase with the proper grade and quantity of engine oil. Operate the engine and check for leaks.

OIL PUMP DISASSEMBLY

1. Remove the oil inlet tube from the oil pump and remove the gasket.
2. Remove the cover retaining screws, then remove the cover. Remove the inner rotor and shaft assembly, then remove the outer race.

3. Insert a self-threading sheet metal screw of the proper diameter into the oil pressure relief valve chamber cap and pull the cap out of the chamber. Remove the spring and plunger.

OIL PUMP ASSEMBLY

The oil pump assembly is shown in Fig. 80.

1. Oil all parts thoroughly.
2. Install the oil pressure relief valve plunger, spring, and a new cap.
3. Install the outer race, and the inner rotor and shaft assembly. The inner rotor and shaft, and the outer race are serviced as an assembly. One part should not be replaced without replacing the other. Install the cover. Torque the cover retaining screws to 6-9 ft-lbs.
4. Position a new gasket and the oil inlet tube on the oil pump and install the retaining bolts.

OIL PAN CLEANING AND INSPECTION

Scrape any dirt or metal particles from the inside of the pan. Scrape all old gasket material from the gasket surface. Wash the pan in a solvent and dry it thoroughly. Be sure all foreign matter is removed from below the baffle plate.

Check the pan for cracks, holes, damaged drain plug threads, a loose baffle, and a nicked or warped gasket surface.

Repair any damage, or replace the pan if repairs cannot be made.

OIL PUMP CLEANING AND INSPECTION

Wash all parts in a solvent and dry them thoroughly. Use a brush to clean the inside of the pump housing and the pressure relief valve chamber. Be sure all dirt and chips are removed.

Check the inside of the pump housing and the outer race and rotor for damage or excessive wear.

Check the mating surface of the pump cover for wear. If the cover mating surface is worn, scored, or grooved, replace the cover.

Measure the outer race to housing clearance (Fig. 81).

With the rotor assembly installed in the housing, place a straight edge over the rotor assembly and the housing. Measure the rotor end play clearance between the straight edge and the rotor and outer race (Fig. 82).

The outer race, shaft and rotor are replaceable only as an assembly.
Check the drive shaft to housing bearing clearance by measuring the OD of the shaft and the ID of the housing bearing.

Inspect the relief valve spring for a collapsed or worn condition. Check the relief valve spring tension. If the spring tension is not within specifications and/or the spring is defective, replace the spring. Check the relief valve piston for scores and free operation in the bore.

6 WORK STAND REPAIR OPERATIONS

To perform the operations in this section, it will be necessary to remove the engine from the car and install it on a work stand (Page 1-17).

CRANKSHAFT

REMOVAL

The crankshaft and related parts are shown in Fig. 83.

1. Remove the generator adjusting arm bracket bolt from the generator and the upper support bracket bolt at the water pump. Remove the spark plugs to allow easy rotation of the crankshaft.

2. Remove the fuel pump. Slide the water pump by-pass hose clamp toward the rear of the engine. Remove the water pump and fan as an assembly.

3. Remove the crankshaft damper, cap screw and washer. Install the pulley on the damper (Fig. 53) and remove the damper.

4. If the crankshaft sleeve is not stepped down (the same OD on both ends), remove it as shown in Fig. 54. If the sleeve is stepped down, remove it with a three-jawed puller (tool 7675-N).

5. Remove the cylinder front cover.

6. Remove the oil slinger. Check the timing chain deflection, then remove the timing chain and sprockets by following steps 13 thru 18 under “Cylinder Front Cover Removal” on page 1-27.

7. Invert the engine on the work stand. Remove the flywheel. Remove the oil pan and gasket. Remove the oil pump.

8. Make sure all bearing caps (main and connecting rod) are marked so that they can be installed in their original locations. Remove the connecting rod bearing caps. Turn the crankshaft until the connecting rod from which the cap is being removed is down and remove the cap. Push the connecting rod and piston assembly up into the cylinder.

9. Remove the main bearing caps.

10. Carefully lift the crankshaft out of the block so that the thrust bearing surfaces are not damaged. Handle the crankshaft with care to avoid possible fracture or damage to the finished surfaces.

INSTALLATION

1. Remove the rear journal oil seal from the block and rear main bearing cap. Remove the rear main bearing cap to block side seals.

2. Remove the main bearing inserts from the block and bearing caps.

3. Remove the connecting rod bearing inserts from the connecting rods and caps.

4. If the crankshaft main bearing journals have been refinished to a definite undersize, install the correct undersize bearings. Be sure the bearing inserts and bearing bores are clean. Foreign material under the in-

---

**FIG. 83—Crankshaft and Related Parts**
FIG. 84—Seal To Block Installation

Inserts may distort the bearing and cause a failure.

5. Place the upper main bearing inserts in position in the bores with the tang fitting in the slot provided.

6. Install the lower main bearing inserts in the bearing caps.

7. Install a new rear journal oil seal in the block (Fig. 84). After installation, cut the ends of the seals flush.

8. Carefully lower the crankshaft into place. Be careful not to damage the bearing surfaces.

9. Check the clearance of each main bearing as follows:

Place a piece of Plastigage on the crankshaft journal the full width of the journal and about ¼ inch off center (Fig. 85). Follow steps 10 thru 12 under "Main Bearing Replacement" (page 1-32).

10. After the bearings have been fitted, apply a light coat of engine oil to the journals and bearings. Install a new seal in the rear main bearing cap and install the rear main bearing cap by following steps 3 thru 7 under "Crankshaft Lower Rear Oil Seal Replacement" (page 1-31). Install all the bearing caps, except the thrust bearing cap (No. 3 bearing). Be sure that the main bearing caps are installed in their original locations. Torque the bearing cap bolts to 95-105 ft-lbs.

11. Install the thrust bearing cap with the bolts finger-tight.

12. Pry the crankshaft forward against the thrust surface of the upper half of the bearing (Fig. 86).

13. Hold the crankshaft forward and pry the thrust bearing cap to the rear (Fig. 86). This will align the thrust surfaces of both halves of the bearing.

14. Retain the forward pressure on the crankshaft. Tighten the cap bolts to 95-105 ft-lbs (Fig. 86).

15. Force the crankshaft toward the rear of the engine.

16. Install a dial indicator so that the contact point rests against the crankshaft flange and the indicator

FIG. 86—Thrust Bearing Alignment

Fig. 85—Installing & Measuring Plastigage—Engine Removed

axis is parallel to the crankshaft axis (Fig. 87).

17. Zero the dial indicator. Push the crankshaft forward and note the reading on the dial.

If the end play exceeds the wear limit, replace the thrust bearing. If the end play is less than the minimum limit, inspect the thrust bearing faces for scratches, burrs, nicks, or dirt. If the thrust faces are not defective or dirty, they probably were not aligned properly. Install the thrust bearing and align the faces following the recommended procedure (steps 11, 12, 13, and 14), then check the end play.

18. Install new bearing inserts in the connecting rods and caps. Check the clearance of each bearing by following the procedure on page 1-32.

19. After the connecting rod bearings have been fitted, apply a light coat of engine oil to the journals and bearings.

20. Turn the crankshaft throw to the bottom of its stroke. Push the piston all the way down until the rod

FIG. 87—Crankshaft End Play
bearings seats on the crankshaft journal.

21. Install the connecting rod cap. Torque the nuts to 40-45 ft-lbs.

22. After the piston and connecting rod assemblies have been installed, check the side clearance between the connecting rods on each connecting rod crankshaft journal (Fig. 69).

23. Clean the oil pan, oil pump, and oil pump screen. Install the oil pump, oil pan, and oil filter.

24. Position the flywheel on the crankshaft. Install the retaining bolts. Torque the bolts to 75-85 ft-lbs.

25. Install the timing chain and sprockets, cylinder front cover and crankshaft damper, following steps 1 thru 8 under "Cylinder Front Cover Installation" on page 1-28.

26. Install the oil filter, fuel pump, and carburetor fuel inlet line. Install the generator. Install the spark plugs.

27. Remove the engine from the work stand and install in the car (page 1-18).

CLEANING AND INSPECTION

Handle the crankshaft with care to avoid possible fractures or damage to the finished surfaces. Clean the crankshaft with solvent, then blow out all oil passages with compressed air.

Inspect main and connecting rod journals for cracks, scratches, grooves, or scores. Dress minor imperfections with an oilstone. Refinish severely marred journals.

Measure the diameter of each journal in at least four places to determine out-of-round, taper, or undersize condition (Fig. 88).

If the journals exceed the wear limit, they should be refinished to size for the next undersize bearing.

A VS B = VERTICAL TAPER
C VS D = HORIZONTAL TAPER
A VS C AND B VS D = OUT-OF-ROUND
CHECK FOR OUT-OF-ROUND AT EACH END OF JOURNAL

FIG. 88—Crankshaft Journal Measurements

FIG. 89—Camshaft Bearing Replacement

Refinishing Journals. Refinish the journal to give the proper clearance with the next undersize bearing. If the journal will not "clean up" to give the proper clearance with the maximum undersize bearing available, replace the crankshaft.

Always reproduce the same journal shoulder radius that existed originally. Too small a radius will result in fatigue failure of the crankshaft. Too large a radius will result in bearing failure due to radius ride of the journal.

After refinishing the journals, chamfer the oil holes, then polish the journal with a No. 320 grit polishing cloth and engine oil. Crocus cloth may be used also as a polishing agent.

CAMSHAFT BEARING REPLACEMENT

The bearings are available prefinished to size for standard and 0.015-inch undersize journal diameters. The bearings are not interchangeable from one bore to another.

1. Remove the camshaft, the flywheel and the crankshaft. Push the pistons to the top of the cylinders.

2. Remove the camshaft rear bearing bore plug (page 1-30). Remove the camshaft bearings (Fig. 89).

3. Position the new bearings at the bearing bores, and press them in place with the tool shown in Fig. 89.

INSTALL FRONT BEARING 0.005-0.020 INCH BELOW FRONT FACE OF BLOCK

FIG. 90—Camshaft Front Bearing Measurement

Align the oil holes in the bearings with the oil holes in the cylinder block when the bearings are installed. Be sure the camshaft front bearing is installed 0.005-0.020 inch below the front face of the cylinder block (Fig. 90).

4. Clean out the camshaft rear bearing bore plug recess thoroughly. Coat the flange of a new plug with water resistant sealer and install the plug (Fig. 91).

5. Install the camshaft, crankshaft, flywheel, and related parts. Install the engine in the car.

ENGINE DISASSEMBLY

1. Install the engine on the work stand (Fig. 25).

2. Remove the distributor cap and spark plug wire assembly.

3. Disconnect the distributor vacuum line at the distributor. Remove the carburetor fuel inlet line. Remove the fuel pump and discard the gasket.

4. Slide the clamp on the water
pump by-pass hose toward the water pump. Remove the automatic choke heat tube. Remove the valve rocker arm covers.

5. Crank the engine until the No. 1 piston is at TDC at the end of the compression stroke. Rotate the crankshaft damper an additional 45° (identified on the damper by "XX"). Starting at the No. 4 cylinder, loosen the right rocker arm shaft support bolts in sequence, two turns at a time. After the bolts are all loosened, remove the valve rocker arm shaft assembly and the oil baffle plate. Starting at the No. 5 cylinder, follow the same procedure on the left valve rocker arm shaft support bolts. This procedure must be followed to avoid damage to the valve mechanism.

6. Remove the valve push rods in sequence and put them in a rack so that they can be installed in their original bore.

7. Remove the distributor hold down bolt and clamp and remove the distributor.

8. Remove the intake manifold retaining bolts.

9. Install standard eye bolts with ⅜-18 threads in the left front and right rear rocker arm cover screw holes and attach the engine lifting sling (Fig. 24).

10. Raise the manifold and carefully remove it from the engine. Discard the intake manifold gaskets and seals.

11. Remove the baffle plate from the valve push rod chamber floor by prying up on the baffle with a screw driver (Fig. 92).

12. Lift the valve lifters from the cylinder block and place them in a rack so that they can be installed in their original bore (Fig. 93). The internal parts of each hydraulic valve lifter assembly are matched sets. Do not intermix the parts. Keep the assemblies intact until they are to be cleaned.

13. Remove the exhaust manifolds and the spark plugs.

14. Remove the cylinder head bolts, and then install the cylinder head holding fixtures (Fig. 34).

15. Lift the cylinder heads off the block. Do not pry between the head and the block. Discard the cylinder head gaskets.

16. Remove the oil filter. Remove the oil filter adapter assembly and oil pressure sending unit as an assembly. Discard the gasket.

17. Remove the generator, brackets, and drive belts.

18. Remove the water pump, pulley, and fan as an assembly.

19. Remove the power steering pulley. Remove the crankshaft damper (Fig. 53).

20. If the crankshaft sleeve is not stepped down (the same OD on both ends), remove it as shown in Fig. 54. If the crankshaft sleeve is stepped down (different OD on each end), remove it with a three-jawed puller (tool 7675-N).

21. Remove the cylinder front cover. Discard the gasket. Remove the crankshaft front oil slinger.

22. Check the timing chain deflection by following steps 13, 14, and 15 under "Cylinder Front Cover and Timing Chain Removal" on page 1-27.

23. Remove the camshaft thrust button and spring, the sprocket cap screw, and thrust button spring retainer, and the fuel pump eccentric. Remove the crankshaft sprocket key.

Remove the sprockets and timing chain as an assembly (Fig. 57).

24. Remove any ridge and/or carbon deposits from the upper end of the cylinder bores. Move the piston to the bottom of its travel and place a cloth on the piston head to collect the cuttings. Remove the cylinder ridge with a ridge cutter. Follow the instructions furnished by the tool manufacturer. Never cut into the ring travel area in excess of 1/32 inch when removing ridges. After the ridge has been removed, remove the cutter from the cylinder bore.

25. Remove the flywheel.

26. Invert the engine. Remove the oil pan. Discard the gasket.

27. Remove the oil pump and inlet tube as an assembly. Remove the oil pump drive shaft. Discard the oil pump gasket.

28. Make sure all connecting rods and caps are marked so that they can be installed in their original locations. Turn the crankshaft until the connecting rod being removed is down. Remove the rod cap.

29. Push the connecting rod and piston assembly out the top of the cylinder with the handle end of a hammer. Avoid damage to the crankpin or the cylinder wall when removing the piston and rod.

30. Remove the bearing inserts from the connecting rods and caps. Install the rod caps on the connecting rods from which they were removed.

31. Remove the main bearing caps.

32. Carefully lift the crankshaft out of the cylinder block so that the thrust bearing surfaces are not damaged. Handle the crankshaft with care to avoid possible fracture or damage to the finished surfaces.

33. Remove the rear journal oil seal from the block and rear bearing cap, and remove the cap to block side seals.

34. Remove the main bearing inserts from block and bearing caps. Install the main bearing caps in their original positions.

35. Carefully remove the camshaft by pulling it toward the front of the engine. Use caution to avoid damaging the journals and lobes.

36. Remove the camshaft rear bearing bore plug. Remove the camshaft bearings (Fig. 89).
CYLINDER BLOCK

CLEANING AND INSPECTION

Thoroughly clean the block in solvent. Remove old gasket material from all machined surfaces. Remove all pipe plugs which seal oil passages, then clean out all the passages. Blow out all passages, bolt holes, etc. with compressed air. Make sure the threads in the cylinder head bolt holes are clean. Dirt in the threads may cause binding and result in a false torque reading. Use a tap to true-up threads and to remove any deposits.

After the block has been thoroughly cleaned, make a check for cracks. Minute cracks not visible to the naked eye may be detected by coating the suspected area with a mixture of 25% kerosene and 75% light motor oil. Wipe the part dry and immediately apply a coating of zinc oxide dissolved in wood alcohol. If cracks are present, the coating will become discolored at the defective area. Replace the block if it is cracked.

Check all machined gasket surfaces for burrs, nicks, scratches, and scores. Remove minor imperfections with an oil stone. Check the flatness of the cylinder block gasket surface following the procedure and specifications recommended for the cylinder head.

Replace all expansion-type plugs that show evidence of leakage.

Inspect the cylinder walls for scoring, roughness, or other signs of wear. Check the cylinder bore for out-of-round and taper. Measure the bore with an accurate gauge following the instructions of the manufacturer. Measure the diameter of each cylinder bore at the top, middle, and bottom with the gauge placed at right angles and parallel to the centerline of the engine (Fig. 94).

Refinish cylinders that are deeply scored and/or when out-of-round and/or taper exceed the wear limits.

If the cylinder walls have minor surface imperfections, but the out-of-round and taper are within limits, it may be possible to remove the imperfections by honing the cylinder walls and installing new service piston rings providing the piston clearance is within limits. Use the finest grade of honing stone for this operation.

REFINISHING CYLINDER WALLS

Honing is recommended for refinishing cylinder walls only when the walls have minor imperfections, such as light scuffs, scratches, etc. The grade of hone to be used is determined by the amount of metal to be removed. Follow the instructions of the hone manufacturer. If coarse stones are used to start the honing operation, leave enough material so that all hone marks can be removed with the finishing hone which is used to obtain the proper piston clearance.

Cylinder walls that are severely marred and/or worn beyond the specified limits should be refinished. Before any cylinder is refinished, all main bearing caps must be in place and tightened to the proper torque so that the crankshaft bearing bores will not become distorted from the refinish operation.

Refinish only the cylinder or cylinders that require it. All pistons are the same weight, both standard and oversize; therefore, various sized pistons can be intermixed without upsetting engine balance.

Refinish the cylinder with the most wear first to determine the maximum oversize. If the cylinder will not clean up when refinished for the maximum oversize piston recommended, replace the block.

Refinish the cylinder to within approximately 0.0015 inch of the required oversize diameter. This will allow enough stock for the final step of honing so that the correct surface finish and pattern are obtained. Use clear sharp hone of No. 220-280 grit for this operation.

For the proper use of the refinish equipment, follow the instructions of the manufacturer. Only experienced personnel should be allowed to perform this work.

After the final operation in either of the two refinishing methods described and prior to checking the piston fit, thoroughly wash the cylinder walls with solvent to remove all abrasive particles, then thoroughly dry the walls. Check the piston fit. Mark the pistons to correspond to the cylinders in which they are to be installed. When the refinishing of all cylinders that require it has been completed and all pistons fitted, thoroughly clean the entire block to remove all particles from the bearing bores, oil passages, cylinder head bolt holes, etc. Coat the cylinder walls with oil.

ENGINE ASSEMBLY

1. Remove the glaze from the cylinder bores by following the instructions of the tool manufacturer.
2. Invert the engine on the work stand.
3. Position the new bearings at the bearing bores, and press them in place with the tool shown in Fig. 89. Align the oil holes in the cylinder block when the bearings are installed. Be sure the camshaft front bearing is installed 0.005-0.020 inch below the front face of the cylinder block (Fig. 90).
4. Check the oil passage that feeds the rocker arm shafts for obstructions by squirting oil into the opening on each cylinder bank and observing the flow through the oil holes at Nos. 2 and 4 bearings.
5. Clean out the camshaft rear bearing bore plug recess thoroughly.
6. Coat the flange of a new plug with water resistant sealer and install it with the flange facing out (Fig. 91). Drive the plug in until it is flush or slightly below the casting surface.
7. Oil the camshaft and apply Lubriplate to all lobes, then carefully slide it through the bearings.
8. Be sure that the rear oil seal grooves are clean. Install a new rear journal oil seal in the block (Fig. 84). After installation, cut the ends of the seals flush.
9. If the crankshaft main bearing journals have been refinished to a definite undersize, install the correct undersize bearings. Be sure the bearing inserts and bearing bores are
clean. Foreign material under the inserts may distort the bearing and cause a failure.

Place the upper main bearing inserts in position in the bore with the tang fitting in the slot provided.

10. Install the lower main bearing inserts in the bearing caps.

11. Carefully lower the crankshaft into place. **Be careful not to damage the bearing surfaces.**

12. Check the clearance of each main bearing by following the procedure under "Main Bearing Replacement" (page 1-32).

13. After the bearings have been fitted, apply a light coat of engine oil to the journals and bearings.

14. Be sure that the oil seal grooves in the rear main bearing cap are clean. Install a new journal seal in the cap (Fig. 65). After installation, cut the ends of the seal flush. Apply a thin coating of oil resistant sealer to the rear main bearing cap at the rear of the top mating surface. (Fig. 67). **Do not apply sealer to the area forward of the side seal groove.**

Install the rear main bearing cap and the remainder of the caps, except the thrust bearing cap (No. 3 bearing). **Be sure that the main bearing caps are installed in their original locations.** Torque the bearing cap bolts to 95-105 ft-lbs.

15. Install the thrust bearing cap and check crankshaft end play by following steps 11 thru 17 under "Crankshaft Installation" on page 1-38.

16. Turn the engine on the work stand so that the front end is up.

17. Install the pistons and connecting rods by following steps 1 thru 9 under "Piston and Connecting Rod Installation" on page 1-33.

18. Position the sprockets and timing chain on the camshaft and crankshaft (Fig. 57). Be sure the timing marks on the sprockets are positioned as shown in Fig. 56.

19. Lubricate the timing chain and sprockets with engine oil.

20. Install the fuel pump eccentric (Fig. 58), the camshaft sprocket cap screw, and thrust button spring retainer. Torque the sprocket cap screw to 35-45 ft-lbs. Install the camshaft thrust button spring and thrust button (Fig. 58). Install the crankshaft front oil slinger.

21. Clean the cylinder front cover and the cylinder block gasket surfaces. Install a new crankshaft front oil seal (Fig. 61).

22. Coat the gasket surface of the block and cover and the cover bolt threads with sealer. Position a new gasket on the block.

23. Install the alignment pilot tool on the cylinder front cover so that the keyway in the pilot aligns with the key in the crankshaft. Position the cover and pilot over the end of the crankshaft and against the block (Fig. 60).

24. Install the cylinder front cover bolts finger-tight. Position the generator support bracket and the generator adjusting arm bracket, then install the bolts (on a car equipped with an air conditioner, connect the compressor and brackets to the cylinder front cover). While pushing in on the pilot, torque the cover bolts to 12-15 ft-lbs. Remove the pilot.

25. Lubricate the crankshaft with a white lead and oil mixture and lubricate the oil seal rubbing surface with grease.

26. Install the crankshaft sleeve with the smallest OD end into the cylinder front cover bore if the sleeve is stepped down (different OD on each end).

27. Line up the damper keyway with the key on the crankshaft, then install the damper on the crankshaft (Fig. 60). Install the damper cap screw and washer, and torque the screw to 70-90 ft-lbs.

28. Install the power steering pump pulley on the crankshaft damper.

29. Clean the water pump gasket surfaces and apply sealer. Position new gaskets on the pump and install the water pump, pulley, and fan as an assembly.

30. Using a new gasket, install the fuel pump. Install the generator, brackets, and drive belts.

31. Turn the engine on the work stand so that the top of the engine is up.

32. Clean the cylinder head and block gasket surfaces. Apply sealer to both sides of a new gasket. Guided by the word "FRONT" on the gasket, install the head gasket over the cylinder head dowels.

33. Place the cylinder head on the engine, then remove the holding fixtures. Coat the head bolt threads with water resistant sealer, and then install the bolts.

34. The cylinder head bolt tightening procedure is performed in three progressive steps. Torque the bolts in sequence (Fig. 35) to 70 ft-lbs, then to 80 ft-lbs, and finally to 90 ft-lbs. After the cylinder head bolts have been torqued to specifications, the bolts should not be disturbed.

35. Coat the mating surfaces of the exhaust manifold with a light film of graphite grease.

36. Using a new gasket, install the automatic choke air chamber cover on the right exhaust manifold. **Be sure the cover is securely fastened.** Position the exhaust gas control valve over the muffler inlet pipe studs of the right exhaust manifold, using a new gasket on each side of the valve. Temporarily tie the valve to the exhaust manifold.

37. Position a new gasket over the muffler inlet pipe studs of the left exhaust manifold.

38. Position the exhaust manifolds on the cylinder heads and install the retaining bolts and tab washers. Torque the retaining bolts to 23-28 ft-lbs, working from the center to the ends. Lock the bolts by bending one tab of the washer over a flat on the bolt.

39. Install the spark plugs.

40. Position the baffle plate in the valve push rod chamber. Press it into place (Fig. 95).

41. Coat the outside of each valve lifter with engine oil to provide initial lubrication. **Do not fill the lifters with oil. The lifters will fill much faster after the engine is started, if**

---

**FIG. 95—Baffle Plate Installation**
they are free of any oil film which may cause an oil seal between the plunger and the lifter body. Place each lifter in the bore from which it was removed.

42. Clean the mating surfaces of the intake manifold, cylinder heads, and cylinder block.

43. Coat the intake manifold and cylinder block seal surfaces with oil resistant sealer.

44. Position new seals on the cylinder block and new gaskets on the cylinder heads with the gasket resting on the cylinder head gasket tabs. Be sure the holes in the gaskets are aligned with the holes in the cylinder heads. The correct installation of the gaskets and seals are shown in Fig. 31.

45. Install the eye bolts in the intake manifold and attach the engine lifting sling and carefully lower the intake manifold on the engine (Fig. 29).

46. Position the intake manifold by inserting the distributor in place. After the intake manifold is in place, run a finger around the seal area to make sure the seals are in place. If the seals are not in place, remove the intake manifold and position the seals.

47. Start the water pump by-pass hose on the intake manifold.

48. Be sure the holes in the manifold gaskets and manifold are in alignment. Install the manifold retaining bolts and torque them to 32-35 ft-lbs, working from the center to the ends.

49. Remove the distributor and the engine lifting sling and eye bolts.

50. Refer to “Valve Rocker Arm Shaft Assembly Installation” (page 1-20) and install the valve rocker arm shaft assembly by following steps 1 thru 6.

51. Install the automatic choke heat tube.

52. Rotate the crankshaft damper until the No. 1 piston is on TDC then position the distributor in the block with the rotor at No. 1 firing position and the points open. Install the hold down clamp.

53. Connect the distributor vacuum line. Install the distributor cap. Install the valve rocker arm covers.

54. Connect the spark plug wires. Install the carburetor fuel inlet line.

55. Invert the engine on the work stand. Position the oil pump drive shaft into the distributor socket. With the shaft firmly seated in the distributor socket, the stop on the shaft should touch the roof of the crankcase. Remove the shaft and position the stop as necessary.

56. With the stop properly positioned, insert the oil pump drive shaft into the oil pump.

57. Prime the oil pump by filling either the inlet or outlet port with engine oil. Rotate the pump shaft to distribute the oil within the pump body.

58. Position a new gasket on the pump housing and install the pump and shaft as an assembly. Do not attempt to force the pump into position if it will not seat readily. The drive shaft hex may be misaligned with the distributor shaft. To align, rotate the intermediate shaft into a new position.

59. Position a new gasket on the oil pan and place the oil pan assembly on the block. Install the retaining screws and torque them from the center outward to 9-13 ft-lbs.

60. Position the flywheel on the crankshaft and install the retaining bolts. Torque the bolts to 75-85 ft-lbs.

61. The oil filter assembly is shown in Fig. 80. Clean the oil filter adapter gasket surfaces.

62. Apply sealer to a new adapter gasket, and install the adapter assembly and gasket.

63. Clean the adapter filter recess. Coat the gasket on a new filter with oil. Place the filter in position on the adapter. Hand tighten the filter until the gasket contacts the adapter face, and then advance it 1/2-turn.

64. Install the engine in the car (page 1-18). Operate the engine and check for oil and coolant leaks. Check the ignition timing, adjust the engine idle speed, idle fuel mixture, and anti-stall dashpot.

65. Adjust the transmission control linkage.

### 7 CRANKCASE VENTILATION SYSTEM MAINTENANCE

Refer to Group 16 for the correct mileage interval for maintenance.

**BREATHER CAP**

The breather cap located on the oil filter tube should be cleaned with a solvent at the proper mileage interval.

**POSITIVE CRANKCASE VENTILATION SYSTEM**

At the recommended interval, remove the crankcase ventilation regulator valve, exhaust tube, and connections. Clean the valve and exhaust tube in clean carburetor solvent and dry them with compressed air. Clean the rubber hose connection with a low volatility petroleum base solvent and dry them with compressed air.
